

Energy Efficient Computing: From Bits to Buildings

Horst D. Simon Lawrence Berkeley National Laboratory and EECS Dept., UC Berkeley hdsimon@lbl.gov

The Salishan Conference on High-Speed Computing April 29, 2009

Acknowledgements

A large number of individuals have contributed to energy efficiency in computing at Berkeley Lab, UC Berkeley, and to this presentation:

David Bailey (CRD), Michael Banda (CRD), Michael Bennett (ITD), Shoaib Kamil (CRD), Jonathan Koomey (Stanford), Randy Katz (EECS), Tsu Jae King (EECS), Chuck McParland (CRD), Bruce Nordman (EETD), Lenny Oliker (CRD), Ekow Otoo (CRD), Vern Paxson (UCB/ICSI/CRD), Doron Rotem (CRD), Dale Sartor (EETD), John Shalf (NERSC), Erich Strohmaier (CRD), Bill Tschudi (EETD), Howard Walter (NERSC), Michael Wehner (CRD), Kathy Yelick (NERSC/CRD) ... and many others

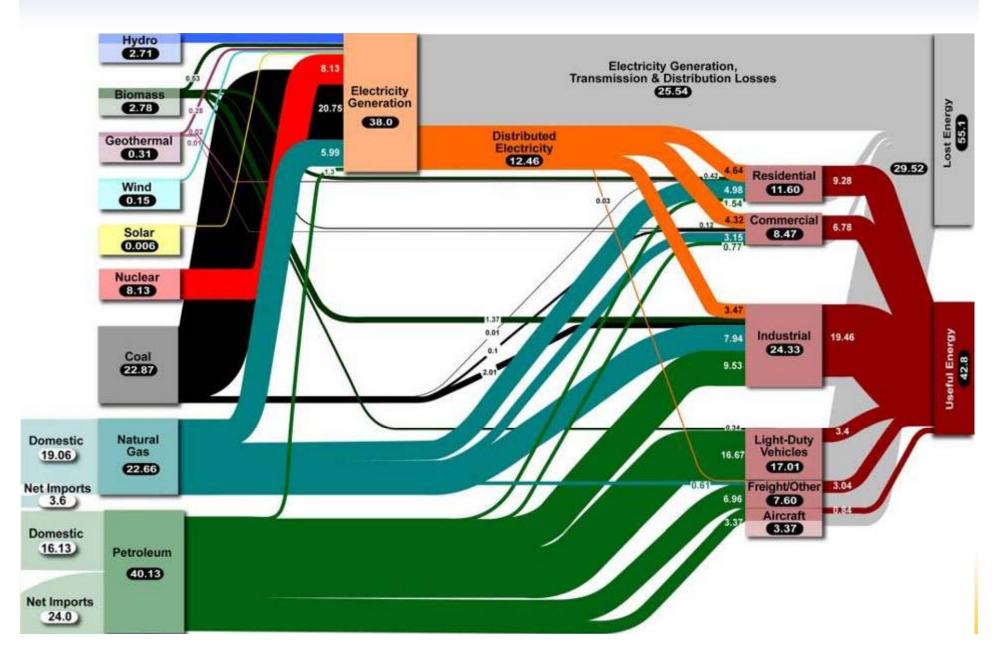

Almost all Berkeley resources about energy efficiency are available at

http://www.lbl.gov/CS/html/energy%20efficient%20co

mputing.html

Energy "Spaghetti" Chart

Power has become an industry-wide issue for computing

Two interrelated issues:

- Building and infrastructure problem -- continued increase in demand for computing ("buildings")
- Computer technology problem
 -- no more power density
 scaling ("bits")

Why does saving energy matter?

Energy Consumption in the United States 1949 - 2005 200 \$ 1.7 175 Trillion Avoided Supply = 70 Quads in 2005 150 125 If E/GDP had dropped 0.4% per year \$ 1.0 100 Trillion New Physical Supply = 25 Q 75 Actual (E/GDP drops 2.1% per year) 50 70 Quads per year saved or avoided corresponds to 1 Billion cars off the 25 road 0 +--1973 1946 2005 Source: Art Rosenfeld, California Energy Commission, http://www.energy.ca.gov/commission/commissioners/rosenfeld_docs/index.html U.S. DEPARTMENT OF rrrrrr Office of Science

BERKELEY I

An Honest Question?

Does the HPC community really care about reducing the carbon footprint?

NO!

HPC Interests

- Energy efficiency in computer rooms
 - Spend more resources on computing than on infrastructure
- Energy efficient technology
 - Maintain performance growth and get things done that could not be done before

Khazzoom-Brookes Postulate

- Energy efficiency at the micro-level leads to higher energy consumption at the macro-level
 - cheaper energy increases use
 - increased energy efficiency leads to economic growth
 - increased efficiency in one bottleneck resource increases use of companion technologies
- HPC follows Khazzoom-Brookes

Energy and IT

- "Big IT" all electronics
 - PCs / etc., consumer electronics, telephony
 - Residential, commercial, industrial
 - More than 200 TWh/year
 - \$16 billion/year
 - Based on .08\$/KWh
 - Nearly 150 million tons of CO₂ per year
 - Roughly equivalent to 30 million cars!

One central baseload power plant (about 7 TWh/yr)

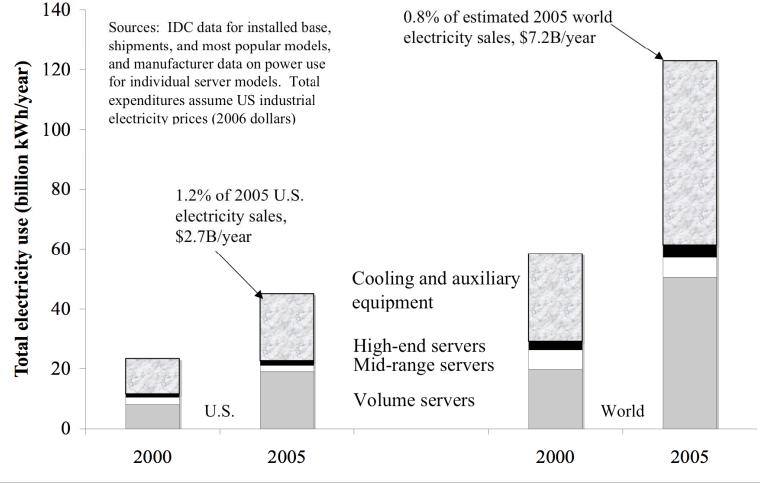

Numbers represent

U.S. only

... and IT electricity use is increasing

data taken from: Jonathan Koomey, "Estimating Total Power Consumption by Servers in the U.S. and the World" Available at: http://www.koomey.com/publications.html

Worldwide IT Carbon Footprint

IT footprints Emissions by sub-sector, 2020

2007 Worldwide IT carbon footprint: 2% = 830 m tons CO₂ Comparable to the global aviation industry

820m tons CO₂

Expected to grow to 4% by 2020

rrrrr

Total emissions: 1.43bn tonnes CO₂ equivalent

360m tons CO₂

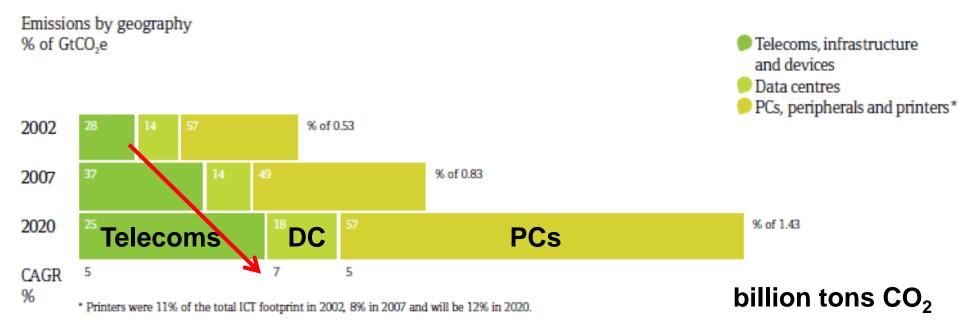

260m tons CO₂

2020 IT Carbon Footprint

"SMART 2020: Enabling the Low Carbon Economy in the Information Age", The Climate Group

Fig. 2.3 The global footprint by subsector

Datacenters: Owned by single entity interested in reducing opex

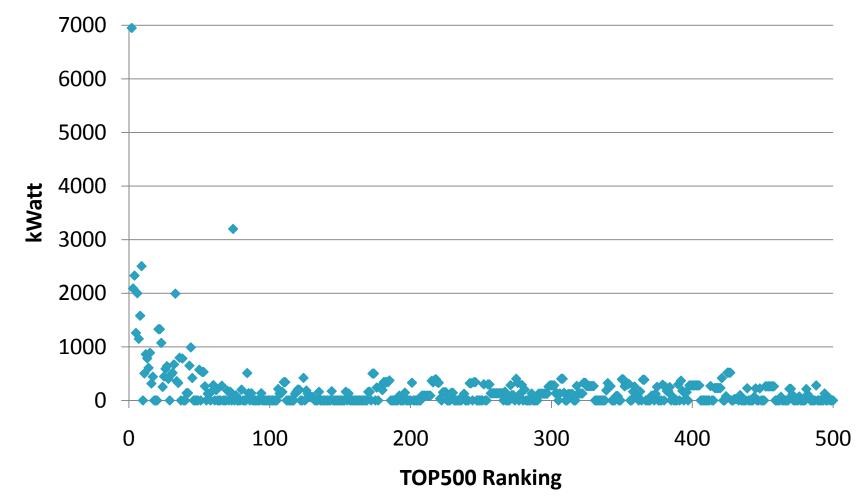

Power has become an industry-wide issue for computing

Two interrelated issues:

- Building and infrastructure problem -- continued increase in demand for computing ("buildings")
- Computer technology problem
 -- no more power density
 scaling ("bits")

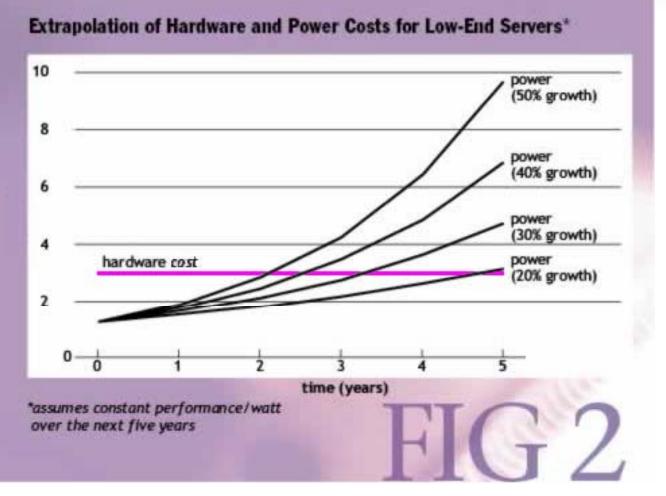

Absolute Power Levels

The Problem

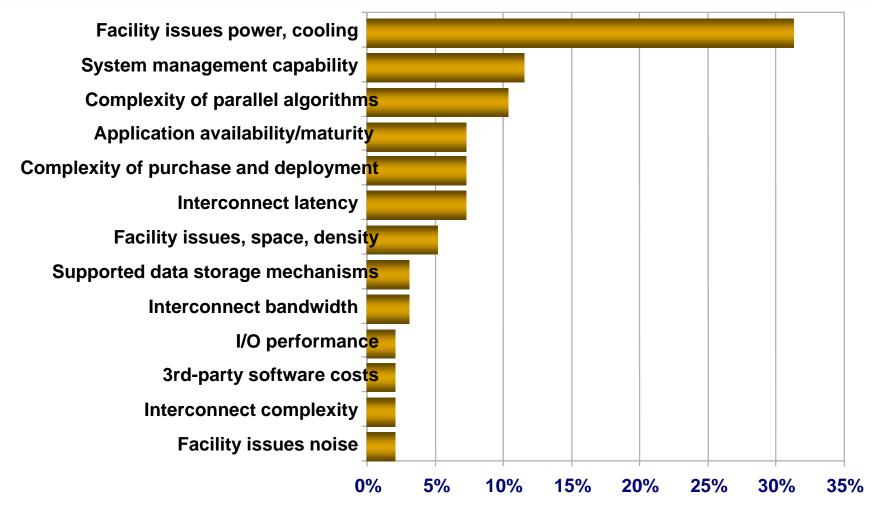

Unrestrained IT power consumption could eclipse hardware costs and put great pressure on affordability, data center infrastructure, and the environment.

Top Challenges to Clusters

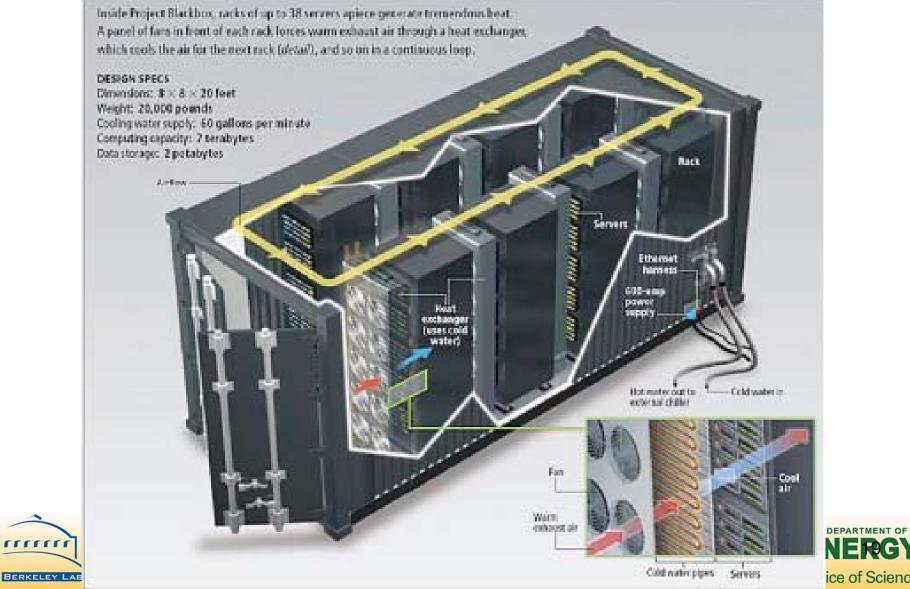

Responses

- Cloud
- Containerized data centers
- Large scale data "factories"
- Increased emphasis on computer room and building efficiency

Containerized Datacenter Mechanical-Electrical Design

ice of Science

Data Center Economic Reality (2006)

- June 2006 Google begins building a new data center near the Columbia River on the border between Washington and Oregon
 - Because the location is "at the intersection of cheap electricity and readily accessible data networking"

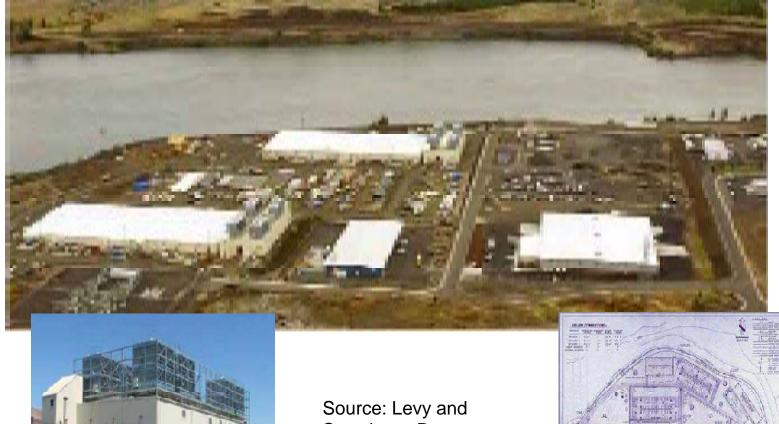

"Hiding in Plain Sight, Google Seeks More Power" by John Markoff, NYT, June 14, 2006

- Microsoft and Yahoo are building big data centers upstream in Wenatchee and Quincy, Wash.
 - To keep up with Google, which means they need cheap electricity and readily accessible data networking

Source: New York Times, June 14, 2006

Google Dalles Oregon Facility 68,680 Sq Ft Per Pod

Source: Levy and Snowhorn, Data Center Power Trends, February 18, 2008

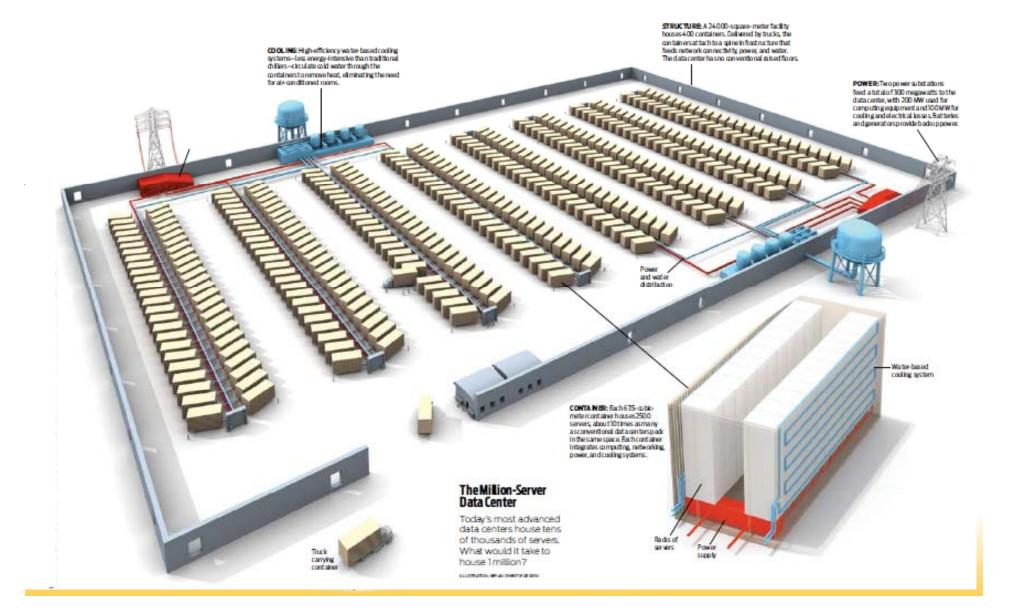

Microsoft Quincy, Wash. 470,000 Sq Ft, 47MW!

Source: Levy and Snowhorn, Data Center Power Trends, February 18, 2008

Microsoft's Chicago Modular Datacenter

The Million Server Datacenter

- 24000 sq. m housing 400 containers
 - Each container contains 2500 servers
 - Integrated computing, networking, power, cooling systems
- 300 MW supplied from two power substations situated on opposite sides of the datacenter
- Dual water-based cooling systems circulate cold water to containers, eliminating need for air conditioned

rooms

Potential Benefits of Improved Data Center Energy Efficiency:

- 20-40% savings typically possible
- Aggressive strategies can yield better than 50% savings
- Extend life and capacity of existing data center infrastructures
- But is my center good or bad?

Benchmarking for Energy Performance Improvement:

Energy benchmarking can allow comparison to peers and help identify best practices

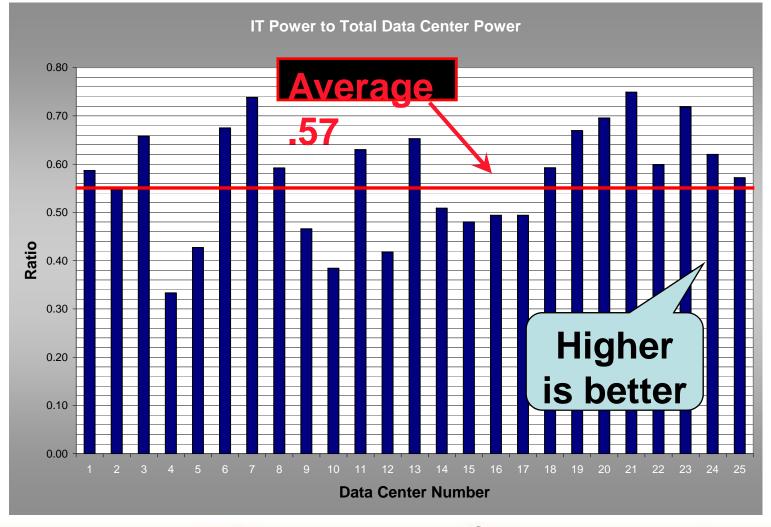

LBNL conducted studies of over 30 data centers:

- Found wide variation in performance
- Identified best practices

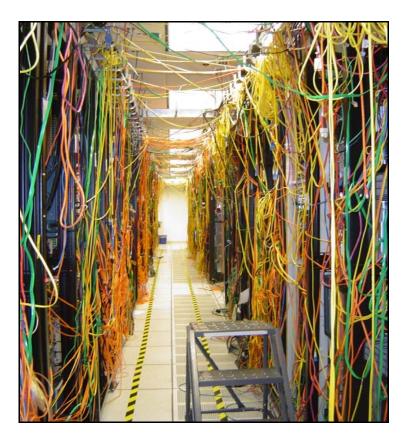

High Level Metric— Data Center Infrastructure Efficiency (DCiE) Ratio of Electricity Delivered to IT Equipment to Total

Using benchmark results to find best practices:

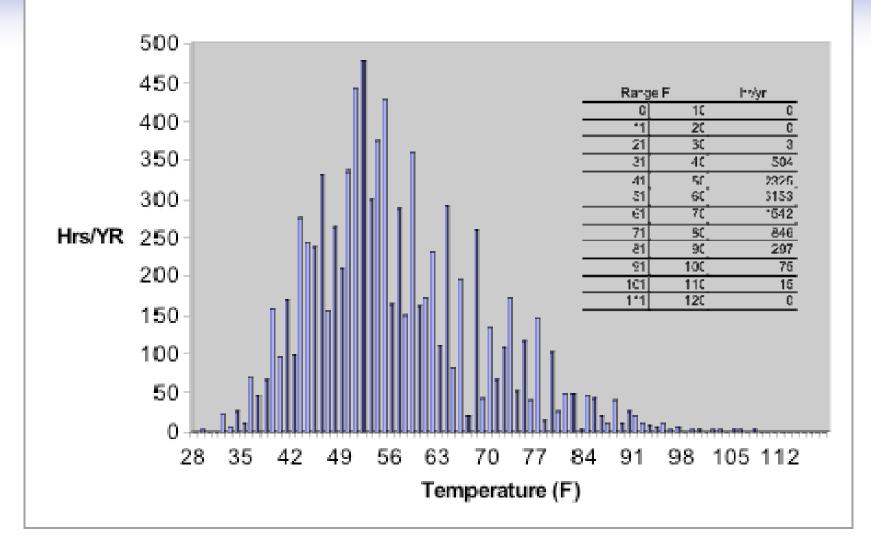

- Air management
- Right-sizing
- Central plant optimization
- Efficient air handling
- Liquid cooling
- Free cooling
- Humidity control
- Improve power chain
- On-site generation
- Design and M&O processes

UC's Computational Research and Theory (CRT) Facility

Berkeley Weather

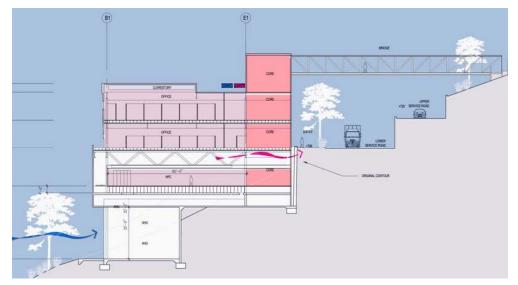

Use Free Cooling:

- Water-side Economizers
 - No contamination question
 - Can be in series with chiller
- Outside-Air Economizers
 - Can be very effective (24/7 load)
 - Must consider humidity

System Design Approach:

- Air-Side Economizer (93% of hours)
- Direct Evaporative Cooling for Humidification/ precooling
- Low Pressure-Drop Design (1.5" total static)

Hours of Operation

Mode 1

Mode 2 Mode 3 Mode 4 Mode 5

total

rrrrr

100% Economiser	2207	hrs
OA + RA	5957	hrs
Humidification	45	hrs
Humid + CH cooling	38	hrs
CH only	513	hrs
	8760	hrs

Water Cooling: Four-pipe System

- Allows multiple temperature feeds at server locations through mixing of CHW & TRW
- Closed-loop treated cooling water from cooling towers (via heat exchanger)
- Chilled water from chillers
- Headers, valves and caps for modularity and future flexibility

Predicted CRT

Performances based on annual energy

DCIE of 0.88 based on peak
 power

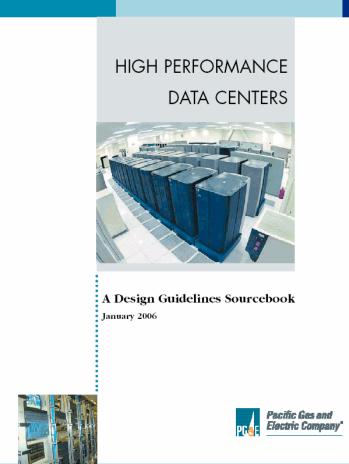

Design Guidelines Are Available

- Design Guides were developed based upon the observed best practices
- Guides are available through PG&E and LBNL websites
- Self benchmarking protocol also available

Power consumption has become an industry-wide issue for computing

Two interrelated issues:

- Building and infrastructure problem -- continued increase in demand for computing
- Computer technology problem
 -- no more power density
 scaling ("bits")

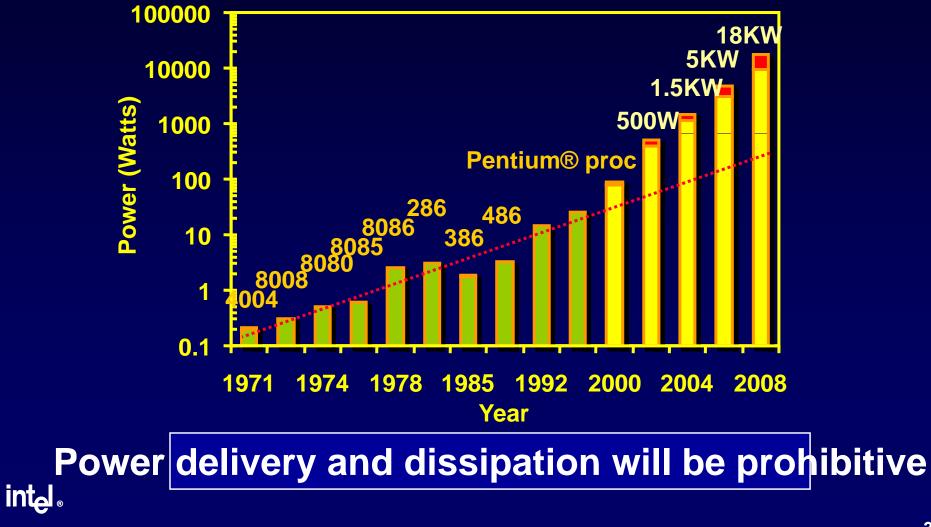

An Early Warning

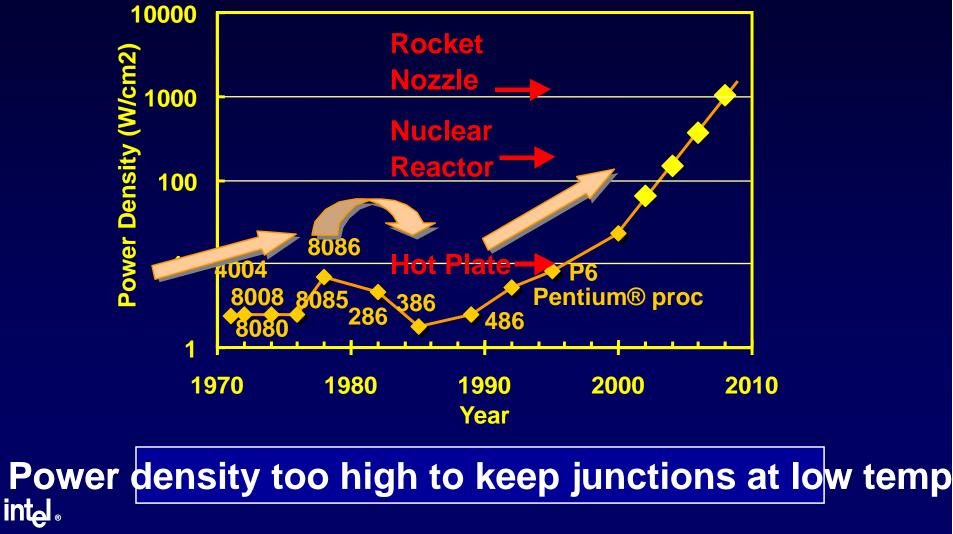

• Presented by Shekhar Borkar in Berkeley in November 2000

Power will be a problem

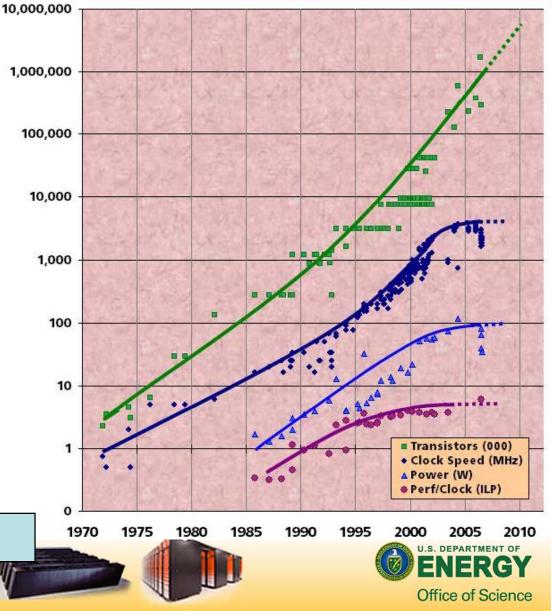

Power density will increase

Traditional Sources of Performance Improvement are Flat-Lining (2004)

- New Constraints
 - 15 years of exponential clock rate growth has ended
- Moore's Law reinterpreted:
 - How do we use all of those transistors to keep performance increasing at historical rates?
 - Industry Response: #cores per chip doubles every 18 months *instead* of clock frequency!
 - multicore

Estimated Exascale Power Requirements

- LBNL IJHPCA Study for ~1/5 Exaflop for Climate Science
 - Extrapolation of Blue Gene and AMD design trends
 - Estimate: 20 MW for BG and 179 MW for AMD
- DOE E3 Report
 - Extrapolation of existing design trends to exascale in 2016
 - Estimate: 130 MW
- DARPA Study
 - More detailed assessment of component technologies for exascale system
 - Estimate: more than 120 MW
- The current approach is not sustainable!

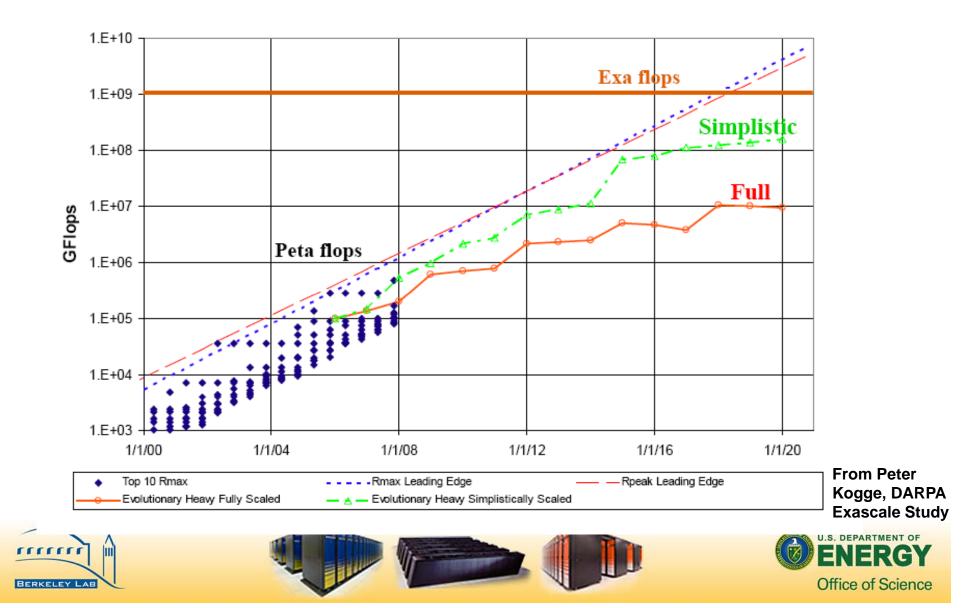

DARPA Exascale Study

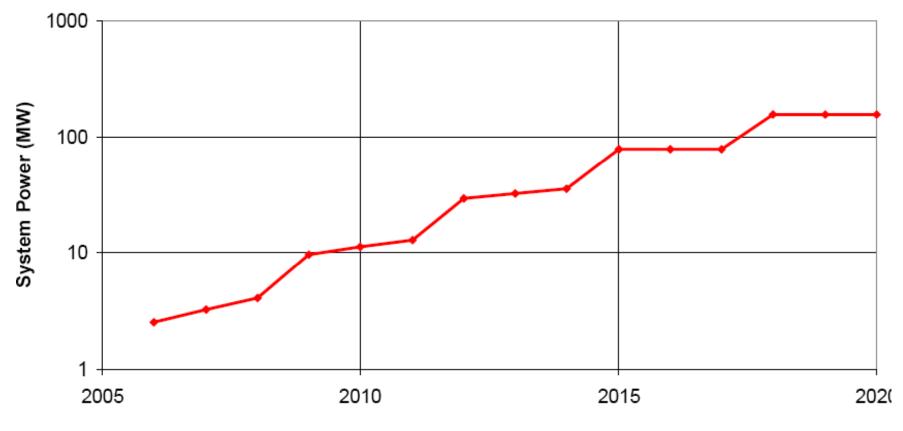

- Commissioned by DARPA to explore the challenges for Exaflop computing
- Two model for future performance growth
 - Simplistic: ITRS roadmap; power for memory grows linear with #of chips; power for interconnect stays constant
 - Fully scaled: same as simplistic, but memory and router power grow with peak flops per chip

We won't reach Exaflops with this approach

... and the power costs will still be staggering

From Peter Kogge, DARPA Exascale Study

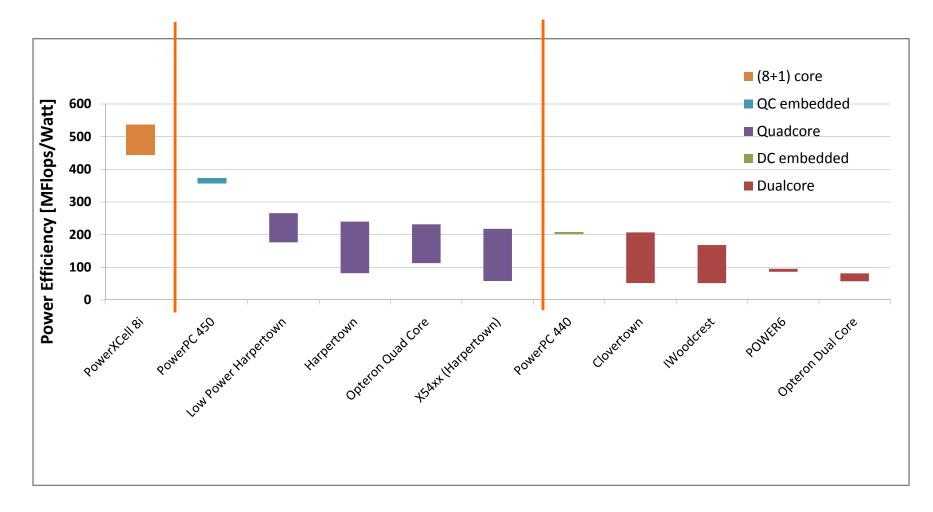

Extrapolating to Exaflop/s in 2018

	BlueGene/L (2005)	Exaflop Directly scaled	Exaflop compromise using expected technology	Assumption for "compromise guess"	
Node Peak Perf	5.6GF	20TF	20TF	Same node count (64k)	
hardware concurrency/node	2	8000	1600	Assume 3.5GHz	
System Power in Compute Chip	1 MW	3.5 GW	35 MW	100x improvement (very optimistic)	
Link Bandwidth (Each unidirectional 3-D link)	1.4Gbps	5 Tbps	1 Tbps	Not possible to maintain bandwidth ratio.	
Wires per unidirectional 3-D link	2	400 wires	80 wires	Large wire count will eliminate high density and drive links onto cables where they are 100x more expensive. Assume 20 Gbps signaling	
Pins in network on node	24 pins	5,000 pins	<u>1,000 pins</u>	20 Gbps differential assumed. 20 Gbps over copper will be limited to 12 inches. Will need optics for in rack interconnects. 10Gbps now possible in both copper and optics.	
Power in network	100 KW	20 MW	4 MW	10 mW/Gbps assumed. Now: 25 mW/Gbps for long distance (greater than 2 feet on copper) for both ends one direction. 45mW/Gbps optics both ends one direction. + 15mW/Gbps of electrical Electrical power in future: separately optimized links for power.	
Memory Bandwidth/node	5.6GB/s	20TB/s	1 TB/s	Not possible to maintain external bandwidth/Flop	
L2 cache/node	4 MB	16 GB	500 MB	About 6-7 technology generations	
Data pins associated with memory/node	128 data pins	40,000 pins	<u>2000 pins</u>	3.2 Gbps per pin	
Power in memory I/O (not DRAM)	12.8 KW	80 MW	4 MW	10 mW/Gbps assumed. Most current power in address bus. Future probably about 15mW/Gbps maybe get to 10mW/Gbps (2.5mW/Gbps is c*v^2*f for random data on data pins) Address power is higher.	
QCD CG single iteration time	2.3 msec	11 usec	15 usec	Requires: 1) fast global sum (2 per iteration) 2) hardware offload for messaging (Driverless messaging)

Power Efficiency related to Processors

Green Flash: Ultra-Efficient Climate Modeling

- Project by Shalf, Oliker, Wehner and others at LBNL
- An alternative route to exascale computing
 - Target specific machine designs to answer a scientific question
 - Use of new technologies driven by the consumer market.

Ultra-Efficient "Green Flash" Computing at NERSC: 100x over Business as Usual

Radically change HPC system development via application-driven hardware/software co-design

- Achieve 100x power efficiency and 100x capability of mainstream HPC approach for targeted high-impact applications
- Accelerate development cycle for exascale HPC systems
- Approach is applicable to numerous scientific applications
- Proposed pilot application: Ultra-high resolution climate change simulation

Path to Power Efficiency Reducing Waste in Computing

- Examine methodology of low-power embedded computing market
 - optimized for low power, low cost and high computational efficiency

"Years of research in low-power embedded computing have shown only one design technique to reduce power: reduce waste."

— Mark Horowitz, Stanford University & Rambus Inc.

- Sources of waste
 - Wasted transistors (surface area)
 - Wasted computation (useless work/speculation/stalls)
 - Wasted bandwidth (data movement)
 - Designing for serial performance

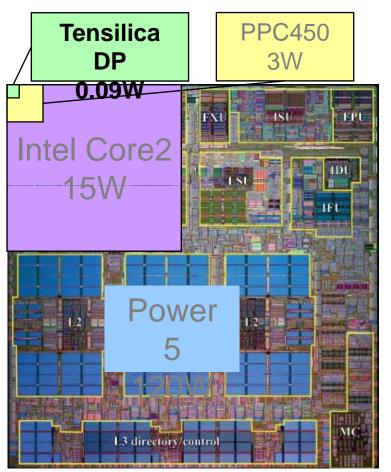

Design for Low Power: More Concurrency

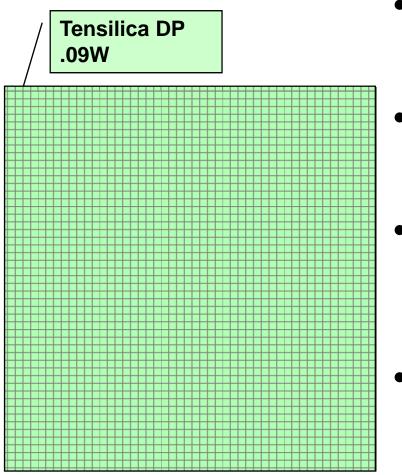

- Cubic power improvement with lower clock rate due to V²F
 - Slower clock rates enable use of simpler cores
 - Simpler cores use less area (lower leakage) and reduce cost
- Tailor design to application to <u>reduce</u> <u>waste</u>

This is how iPhones and MP3 players are designed to maximize battery life

Low Power Design Principles

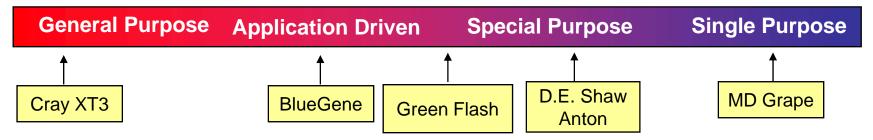

```````

- IBM Power5 (server)
 - 120W@1900MHz
 - Baseline
- Intel Core2 sc (laptop) :
 - 15W@1000MHz
 - 4x more FLOPs/watt than baseline
- IBM PPC 450 (BG/P low power)
 - 0.625W@800MHz
 - 90x more
- Tensilica XTensa (Moto Razor) :
 - 0.09W@600MHz
 - 400x more

Even if each core operates at 1/3 to 1/10th efficiency of largest chip, you can pack 100s more cores onto a chip and consume 1/20 the power

Customization Continuum: Green Flash

- <u>Application-driven does NOT necessitate a special purpose machine</u>
- MD-Grape: Full custom ASIC design
 - 1 Petaflop performance for one application using 260 kW for \$9M
- D.E. Shaw Anton System: Full and Semi-custom design
 - Simulate 100x–1000x timescales vs any existing HPC system (~200kW)
- Application-Driven Architecture (Green Flash): Semicustom design
 - Highly programmable core architecture using C/C++/Fortran
 - Goal of 100x power efficiency improvement vs general HPC approach
 - Better understand how to build/buy application-driven systems
 - Potential: 1km-scale model (~200 Petaflops peak) running in O(5 years)

Green Flash Strawman System Design

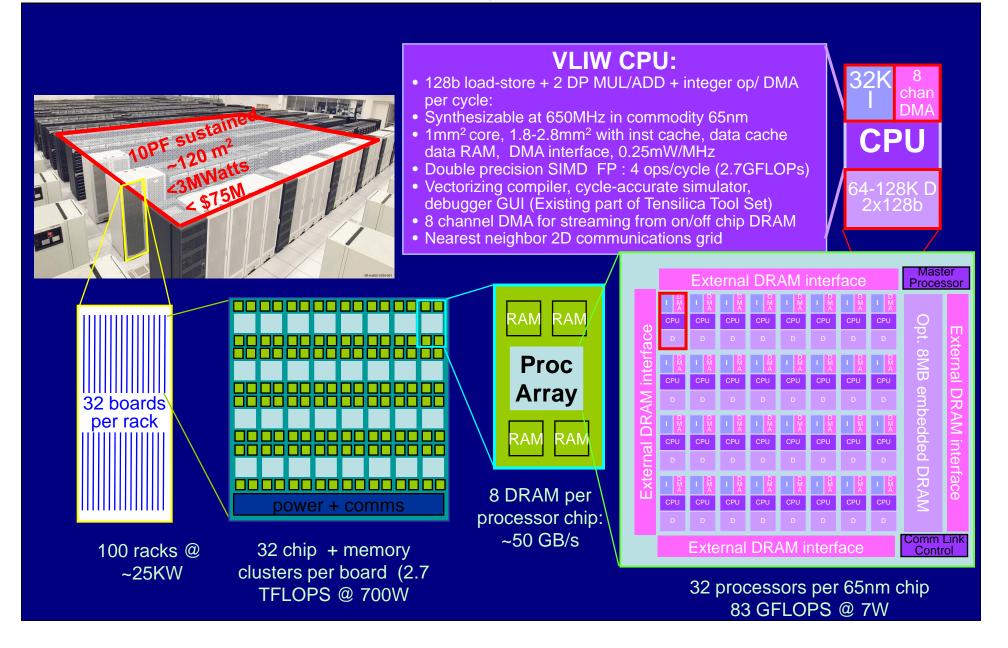

We examined three different approaches (in 2008 technology)

Computation .015°X.02°X100L: 10 PFlops sustained, ~200 PFlops peak

- AMD Opteron: Commodity approach, lower efficiency for scientific applications offset by cost efficiencies of mass market
- BlueGene: Generic embedded processor core and customize system-onchip (SoC) to improve power efficiency for scientific applications
- Tensilica XTensa: Customized embedded CPU w/SoC provides further power efficiency benefits but maintains programmability

Processor	Clock	Peak/ Core (Gflops)	Cores/ Socket	Sockets	Cores	Power	Cost 2008
AMD Opteron	2.8GHz	5.6	2	890K	1.7M	179 MW	\$1B+
IBM BG/P	850MHz	3.4	4	740K	3.0M	20 MW	\$1B+
Green Flash / Tensilica XTensa	650MHz	2.7	32	120K	4.0M	3 MW	\$75M
BERKELEY LAB	U		-		D	and the second sec	NERGY ce of Science

Climate System Design Concept Strawman Design Study

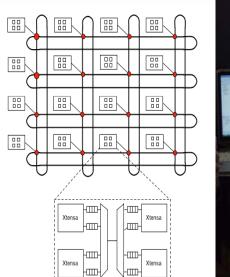

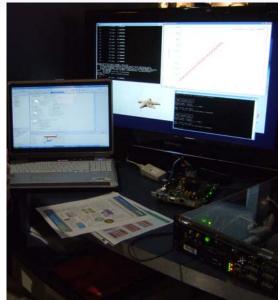

Green Flash Hardware Demo at SC08

- Demonstrated during SC '08
- Proof of concept
 - CSU atmospheric model ported to Tensilica Architecture
 - Single Tensilica processor running atmospheric model at 50MHz
- Emulation performance advantage
 - Processor running at 50MHz
 vs. Functional model at 100 kHz
 - 500x Speedup

CCCCC

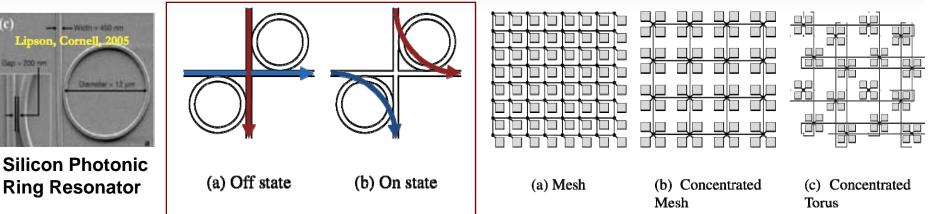

Actual code running - not representative benchmark

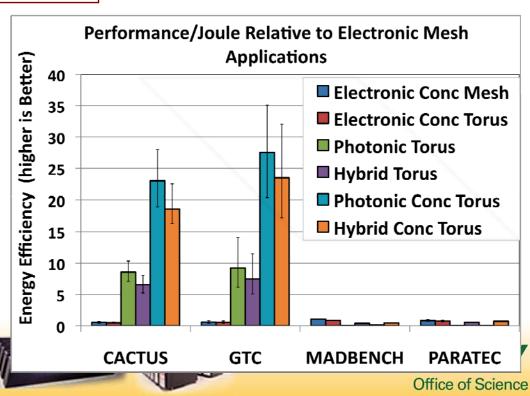

Silicon Photonics for Energy-Efficient Communication

- Silicon photonics enables optics to be integrated with conventional CMOS
- Enables up to 27x improvement in communication energy efficiency!

1111111

Summary

- Power consumption is a huge problem in HPC
 - "Bits": we may not be able to scale to Exaflops without new technologies
 - "Buildings": we may have to spend more \$\$ on infrastructure and less on computing

Outline

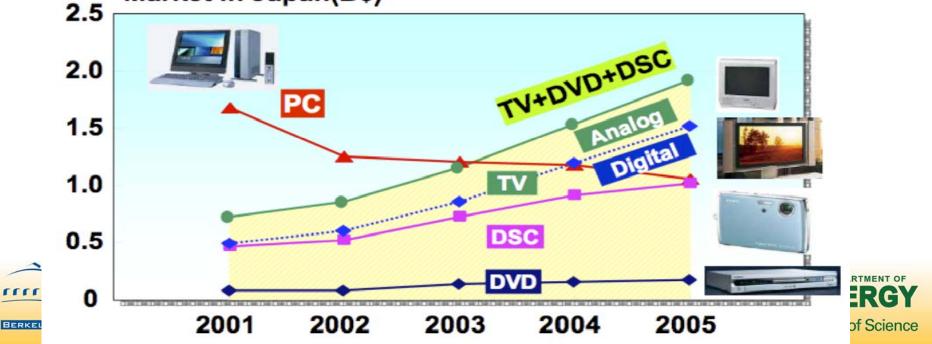

- 1. Power consumption has become an industry-wide issue for computing
- 2. Building and computer room energy efficiency
- 3. Computer architecture for energy efficiency- the Green Flash project

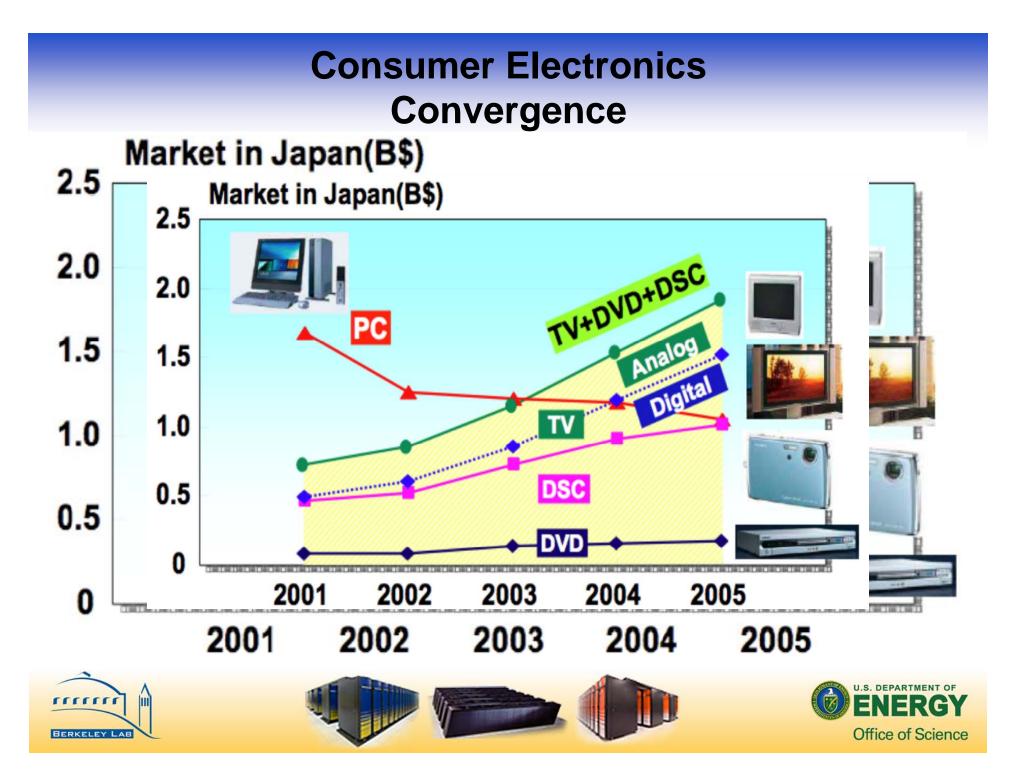

4. Future

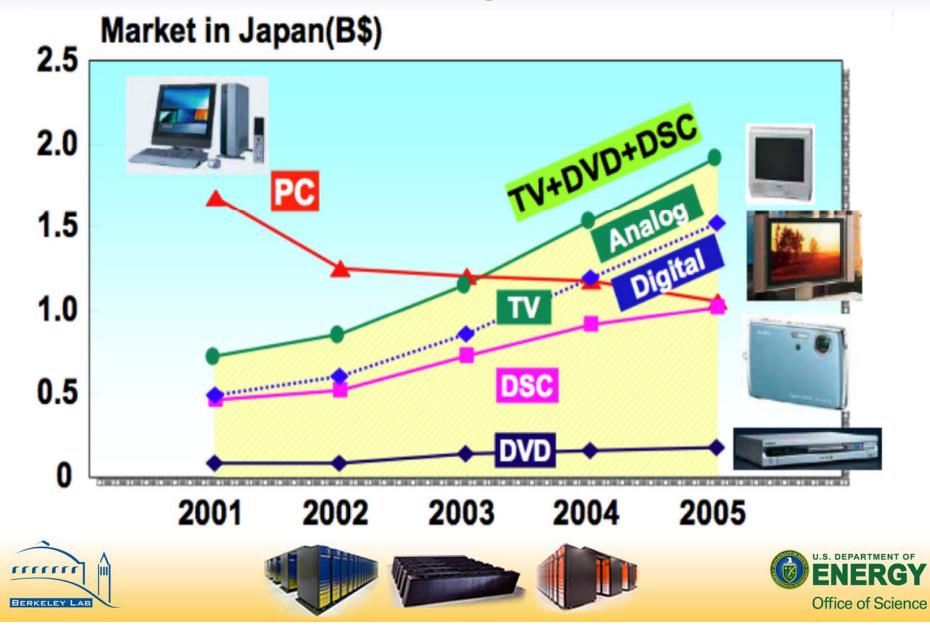

Processor Technology Trend

- 1990s R&D computing hardware dominated by desktop/COTS
 - -Had to learn how to use COTS technology for HPC
- 2010 R&D investments moving rapidly to consumer electronics/ embedded processing
 - Must learn how to leverage embedded processor technology for future HPC systems
 Market in Japan(B\$)

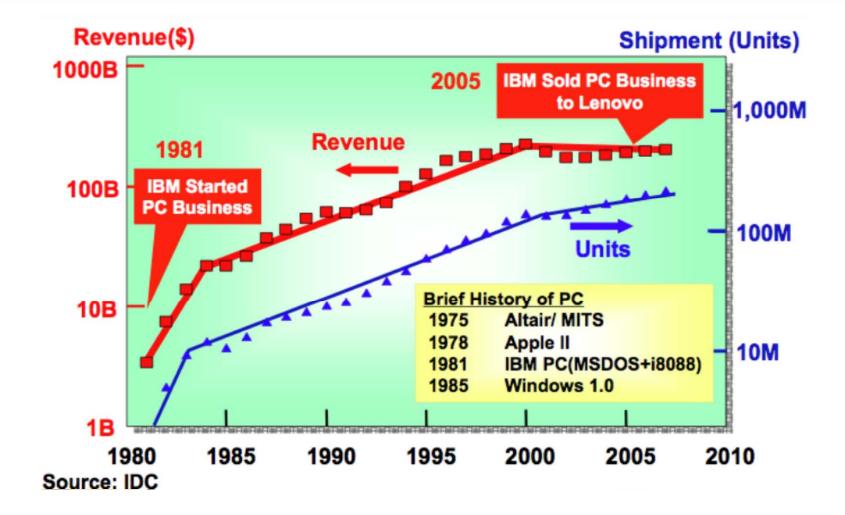

Consumer Electronics Convergence

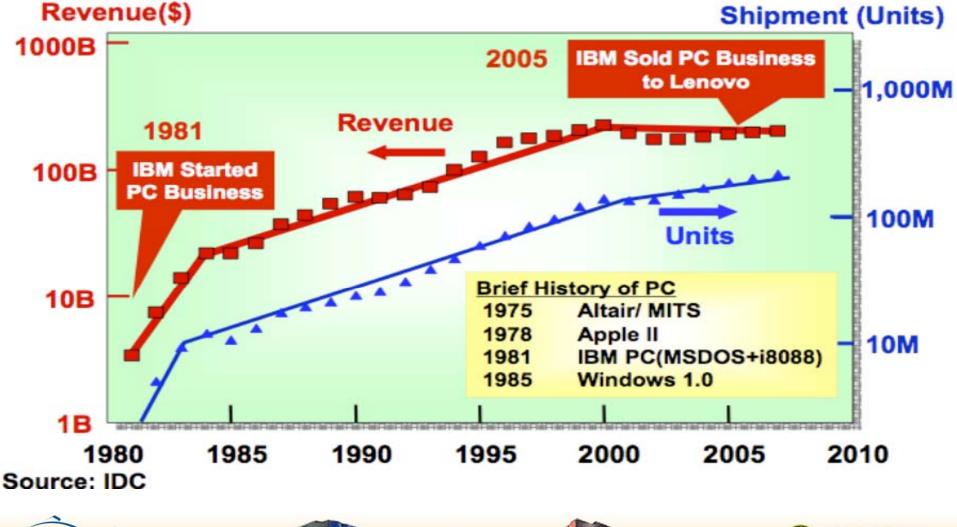

Consumer Electronics has Replaced PCs as the Dominant Market Force in CPU Design!!

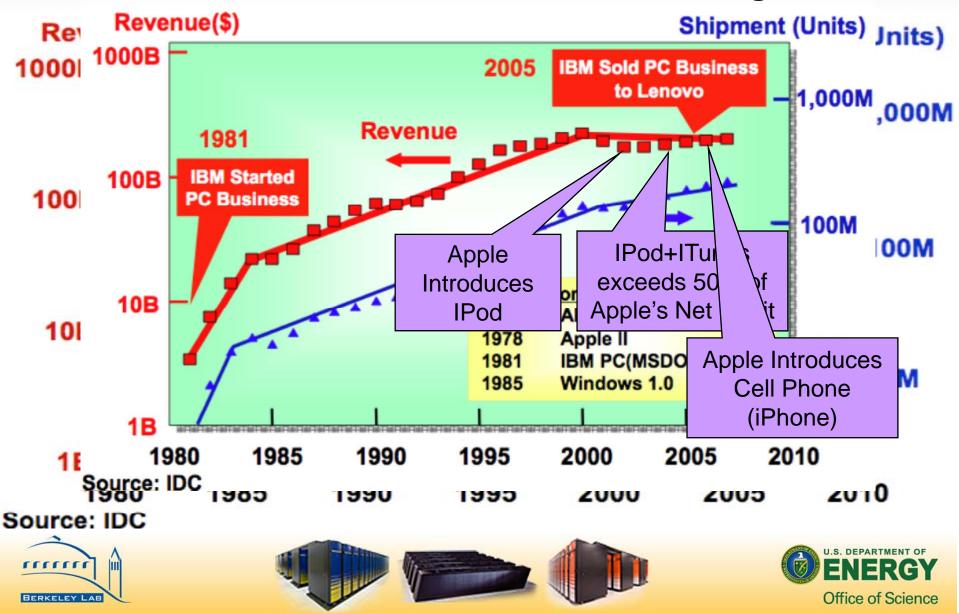

Consumer Electronics has Replaced PCs as the Dominant Market Force in CPU Design!!

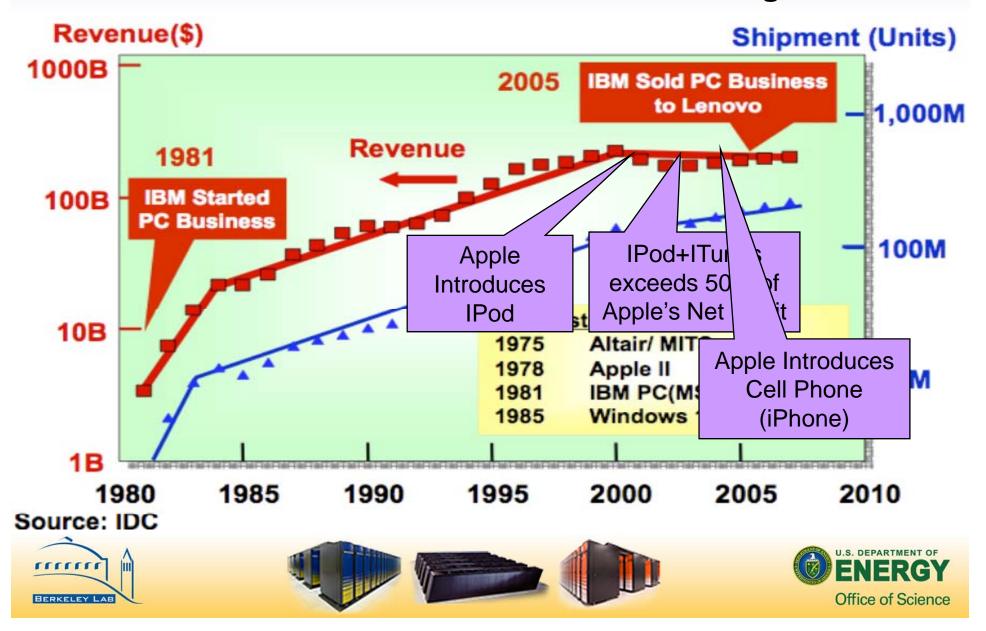

Consumer Electronics has Replaced PCs as the Dominant Market Force in CPU Design!!

Consumer Electronics has Replaced PCs as the Dominant Market Force in CPU Design!!

Power fundamentals 2018--2020

Processor budget: **15 MW** for a sustained HPL Exaflops (10pJ/op) {250}

- Memory budget: 25-50 MW (25 pJ/op) {300} [1/2 Byte/sec/Flops]
- Interconnect budget: **50 MW** (5 pJ/op) [0.1 B/F] {30}
- I/O Budget: **5 MW** (5 pJ/byte) 1 petabyte/sec
- Power and Cooling Budget @30%: 30 MW

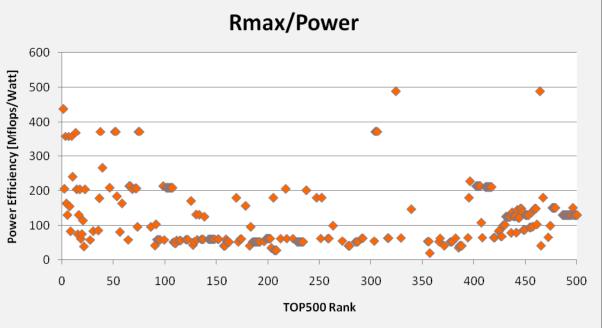

Total Power required 125 MW!

Power Ranking and How Not to do it!

- To rank objects by
 - Weight or Volume
 - Rmax (TOP500)
 - A 'larger' syster
- The ratio of 2 exter
 - (weight/volumne =
 - Performance / Pow
- One can-not 'rank' objects with densities BY SIZE:
 - Density does not tell anything about size of an object
 - A piece of lead is not heavier or larger than one piece of wood.
- Linpack (sub-linear) / Power (linear) will always sort smaller systems before larger ones!

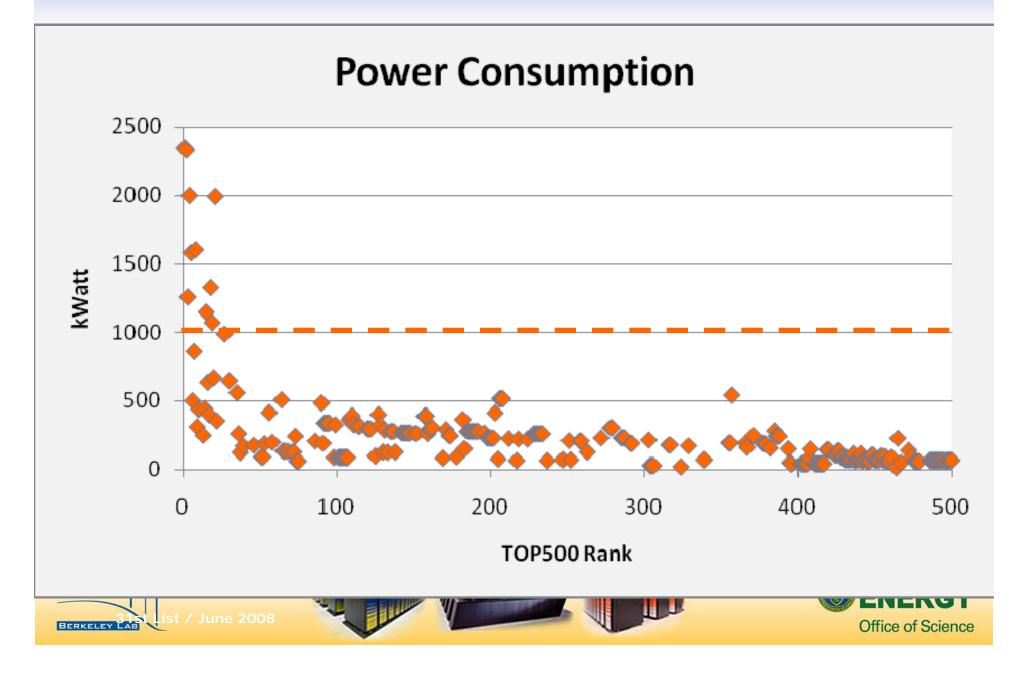

The Transition to Low-Power Technology is Inevitable

Does it make sense to build systems that require the electric power equivalent of an aluminum smelter?

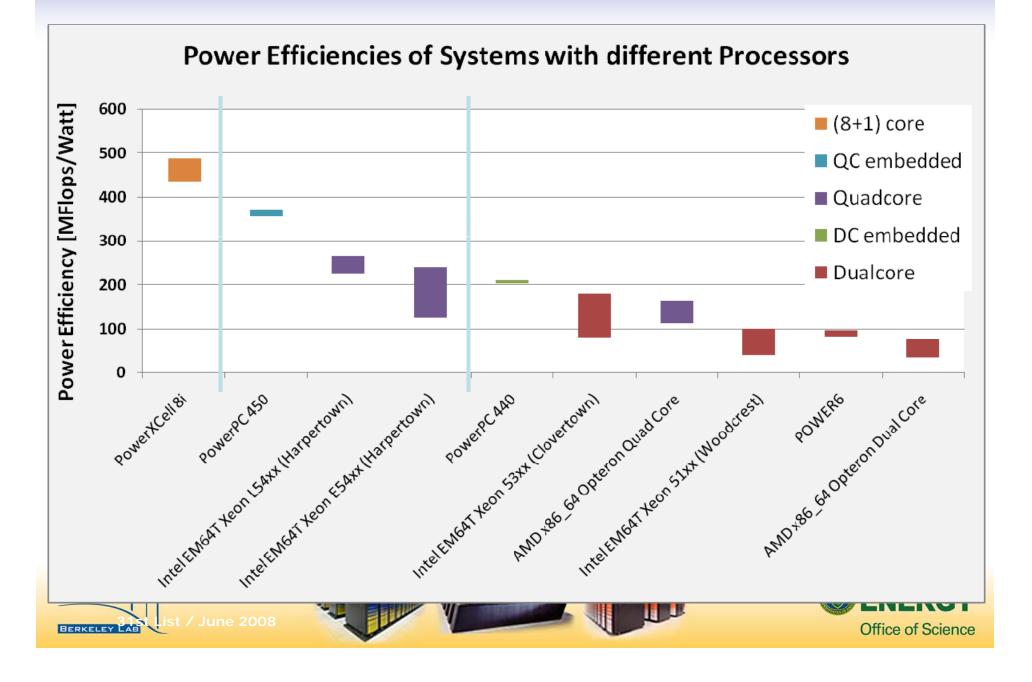

- Information "factories" are only affordable for a few government labs and large commercial companies (Google, MSN, Yahoo ...)
 - Midrange installations will soon hit the 1 2 MW wall, requiring costly new installations
 - Economics will change if operating expenses of a server exceed acquisition cost
- The industry will switch to low-power technology within 2 3 years
- Embedded processors or game processors will be the next step (BG, Cell, Nvidia, SiCortex, Tensilica)
 - Example RR, first Petaflops system

Absolute Power Levels

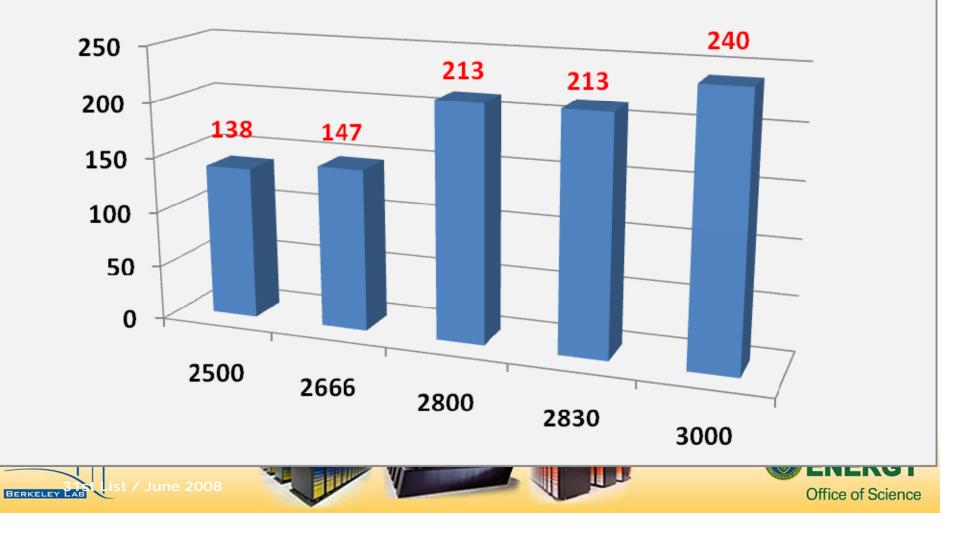

Power Efficiency related to Processors

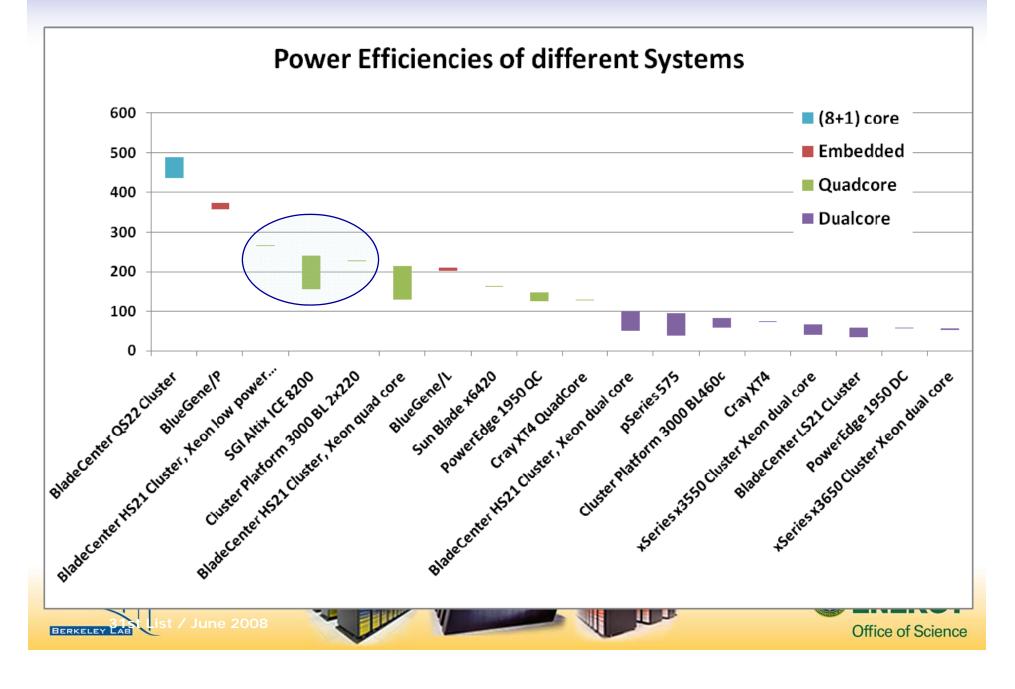

Frequencies and Power Efficiency

Power rating is 80 Watts each!

Maximum Power Efficiency of Harpertown E54xx

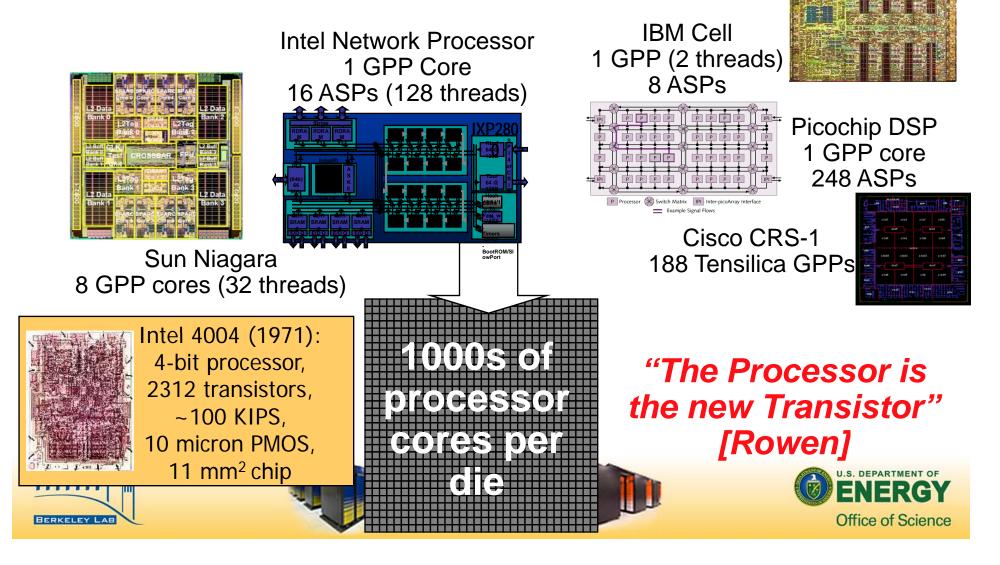

Most Power Efficient Systems

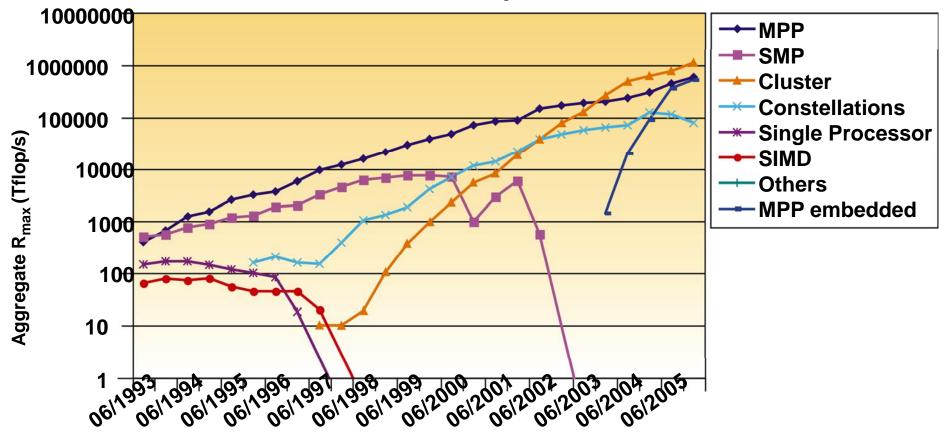

Convergence of Platforms

- Multiple parallel general-purpose processors (GPPs)
- Multiple application-specific processors (ASPs)

BG/L—the Rise of the Embedded Processor

TOP 500 Performance by Architecture

Summary (1)

- LBNL has taken a comprehensive approach to the power in computing problem
 - Component level (investigate use of low-power components and build new system)
 - System level (measuring and understanding energy consumption of system
 - Computer Room level (understand airflow and cooling technology)
 - Building Level (enforce rigorous energy standards in new computer building and use of innovative energy savings technology)

Summary (2)

- Economic factors are driving us already to more energy efficient solutions in computing
- Incremental improvements are well on track, but we may ultimately need revolutionary new technology to reach the Exaflop/s level and beyond

Outline

- 1. Power consumption has become an industry-wide issue for computing
- 2. Building and computer room energy efficiency
- 3. Computer architecture for energy efficiency- the Green Flash project
- 4. Towards a better understanding of "green computing"

Focus on PUE

- PUE = "power usage effectiveness" metric promoted by "Green Grid"
- PUE = total facility power/ computer equipment power
- Reduce PUE by consistent application of facilities improvements

	PUE	
Current Trends	1.9	
Improved Operations		1.7
Best Practices		1.3
State-of-the-Art	1.2
