

# Nuclear level densities for SBSS

-- and can RIA help ?

Bob Haight

LANCE-3

RIA Applications Workshop

October 30-31, 2000

# Outline -- Nuclear level densities

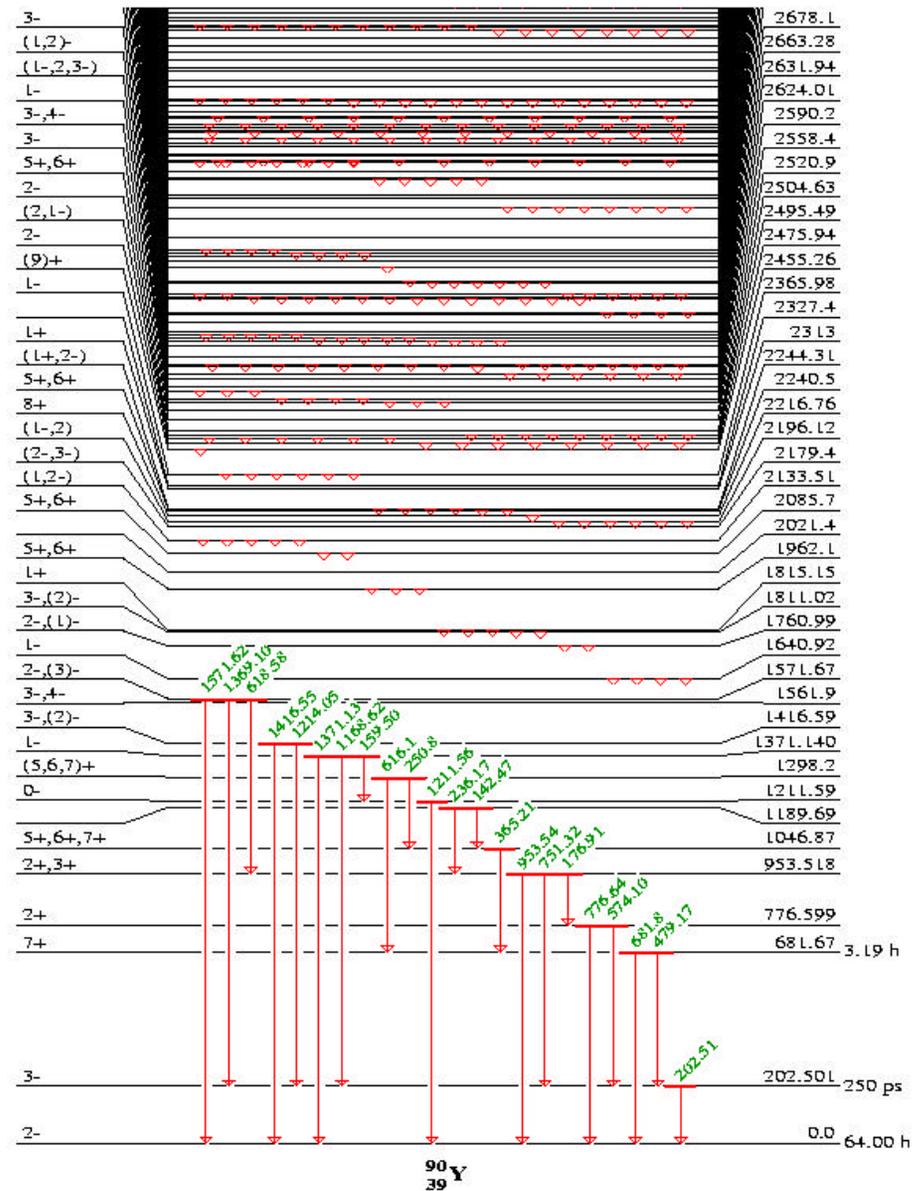

---

- What are they?
- Why are they needed?
- How are they measured?
- Present state of data
- Outstanding problems
- How can RIA address these problems?

Nuclear levels in a  
“typical” nucleus:

*There sure are lots of  
levels!!*

90Y : ADOPTED LEVELS, GAMMAS

The nuclear level density is  
the number of levels  
per unit excitation energy  
at excitation energy  $U$

$$\rho(U)$$

or, better,

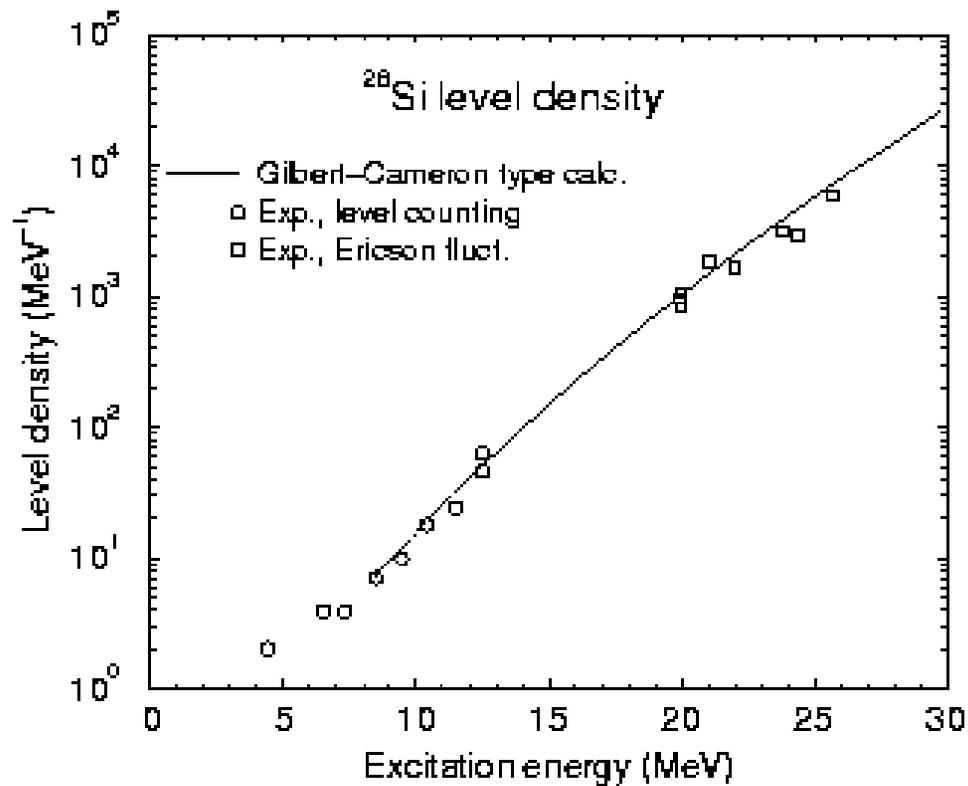

$$\rho(U, J, \pi)$$

or, even better

$$\rho(U, J, \pi, T)$$

# Level densities for silicon -- an example

---

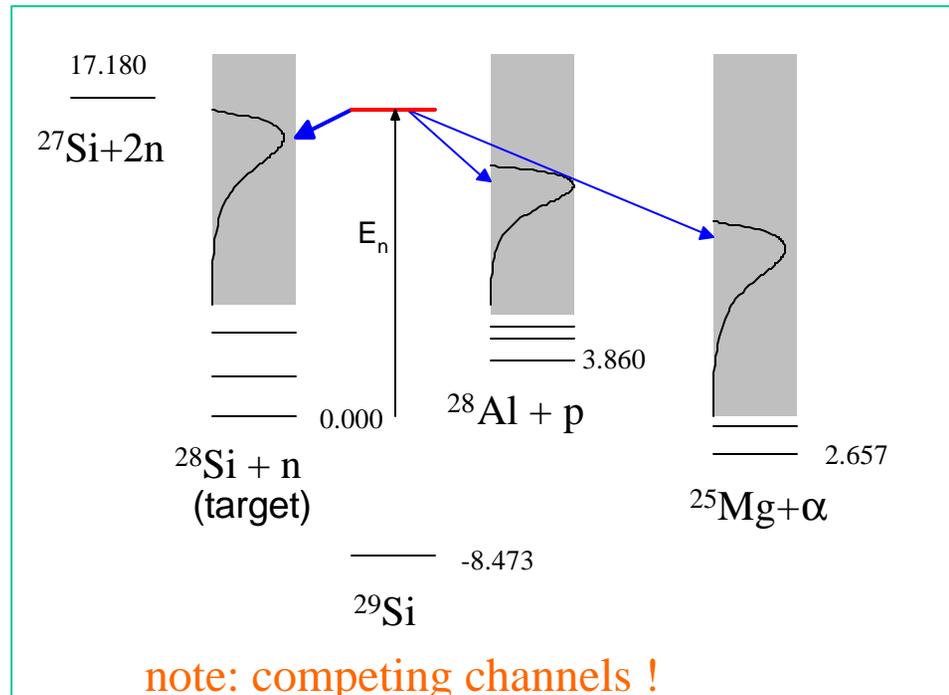

# Why are nuclear level densities interesting?

---

- Basic quantity of many-body quantum-mechanical system
  - Transition from ordered levels to disordered Fermi gas
  - Possibility of observing phase change
- Applications
  - Calculations of cross sections -- esp. for reactions that cannot be measured -- astrophysics, weapons
  - Calculations of radiation effects -- e.g. recoiling nuclei in semiconductors irradiated with neutrons

# Why are level densities needed ?

Answer: to calculate cross sections in order to  
 (1) provide data that cannot be measured  
 (2) resolve discrepancies in existing data

$$S_{c,c'} = S_{c,cn} \cdot \frac{T_{c'}}{S T_{c''}}$$

$$T_{c'} = S T_{c'}(E_n^*) + \int T_{c'}(E_n^*) r(\mathbf{e}) d\mathbf{e}$$

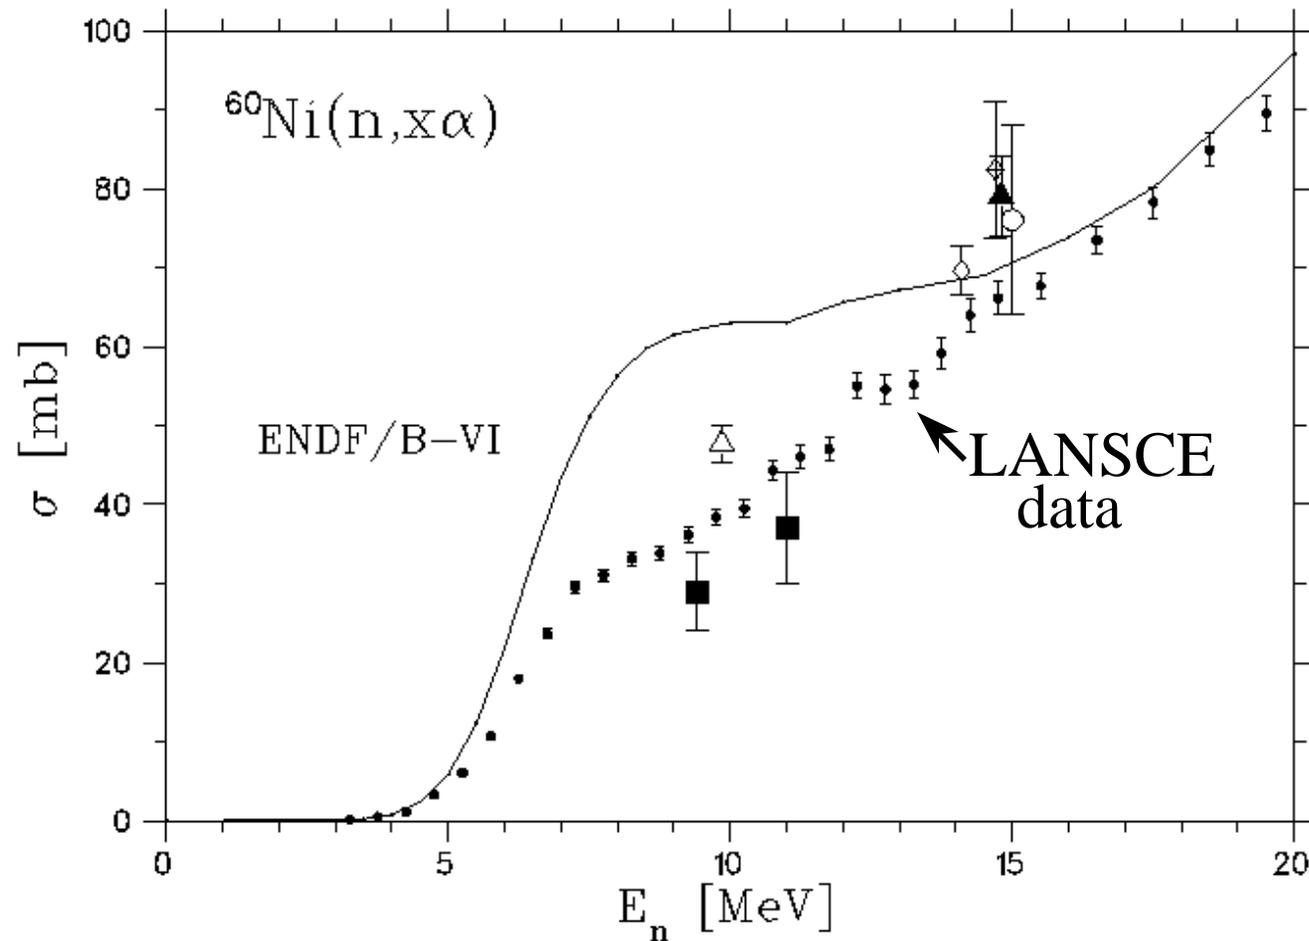

Level density

# How are level densities measured?

---

	RIA ?
Level counting --- > low excitation in nucleus	y
Neutron resonances --- > small region of excitation energy just above the neutron separation energy	n
Fluctuations of cross sections (Ericson fluctuations) --> several MeV above particle separation energy	?
Particle evaporation spectra ---> low energies to particle separation energy	y
Excitation functions ---> relative level densities for competing channels; can go to very high excitation energies	y

# Example of wrong level density (ENDF)

.... and not so bad level densities --

Si + n -> alpha-particle emission cross sections, which are well described by GNASH calculations

# Outstanding problems in nuclear level densities

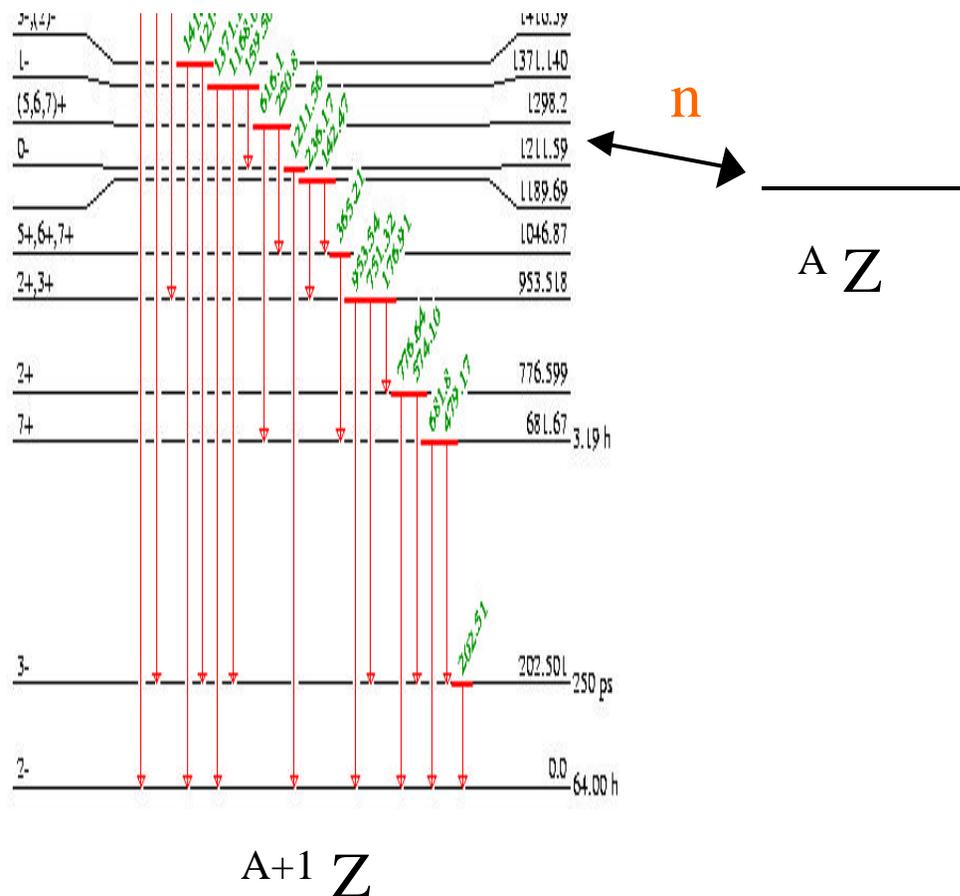

---

- Structure in level densities ?
  - Calculations suggest that there is
  - Transition from ordered levels to disordered Fermi gas guarantees it -- at least up to some excitation energy
- Level densities at high excitation -- where shell and collective effects should wash out
- Angular momentum dependence of level densities
- Parity ratios
- Level densities for nuclides far from stability

# Level density can be very low at neutron separation energy for neutron-rich nuclides

Nuclear levels in a “typical” nucleus very far from the valley of stability

*There sure are a lot fewer bound levels and level density for resonance neutron capture is very low!!*

# How can RIA be used to address these problems ?

---

- Unstable nuclides easily available
  - allows systematic studies across wide range of isotopes
- Beams of nuclides well suited for experiments in inverse kinematics
- Experimental approaches will be extensions of proven techniques

Get level densities through (p,n) reactions in inverse kinematics by measuring neutron emission spectra

(p,n)

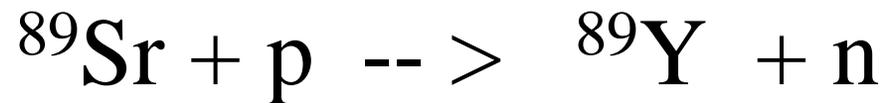

<b><sup>87</sup>Zr</b> T <sub>1/2</sub> =1.68 h 1	<b><sup>88</sup>Zr</b> T <sub>1/2</sub> =83.4 d 3	<b><sup>89</sup>Zr</b> T <sub>1/2</sub> =78.41 h 12	<b><sup>90</sup>Zr</b> T <sub>1/2</sub> =stable	<b><sup>91</sup>Zr</b> T <sub>1/2</sub> =stable	<b><sup>92</sup>Zr</b> T <sub>1/2</sub> =stable	<b><sup>93</sup>Zr</b> T <sub>1/2</sub> =1.53E+6 y 10
<b><sup>86</sup>Y</b> T <sub>1/2</sub> =14.74 h 2	<b><sup>87</sup>Y</b> T <sub>1/2</sub> =79.8 h 3	<b><sup>88</sup>Y</b> T <sub>1/2</sub> =106.65 d 4	<b><sup>89</sup>Y</b> T <sub>1/2</sub> =stable	<b><sup>90</sup>Y</b> T <sub>1/2</sub> =64.10 h 8	<b><sup>91</sup>Y</b> T <sub>1/2</sub> =58.51 d 6	<b><sup>92</sup>Y</b> T <sub>1/2</sub> =3.54 h 1
<b><sup>85</sup>Sr</b> T <sub>1/2</sub> =64.84 d 2	<b><sup>86</sup>Sr</b> T <sub>1/2</sub> =stable	<b><sup>87</sup>Sr</b> T <sub>1/2</sub> =stable	<b><sup>88</sup>Sr</b> T <sub>1/2</sub> =stable	<b><sup>89</sup>Sr</b> T <sub>1/2</sub> =50.53 d 7	<b><sup>90</sup>Sr</b> T <sub>1/2</sub> =28.78 y 4	<b><sup>91</sup>Sr</b> T <sub>1/2</sub> =9.63 h 5
<b><sup>84</sup>Rb</b> T <sub>1/2</sub> =32.77 d 14	<b><sup>85</sup>Rb</b> T <sub>1/2</sub> =stable	<b><sup>86</sup>Rb</b> T <sub>1/2</sub> =18.631 d 18	<b><sup>87</sup>Rb</b> T <sub>1/2</sub> =4.75E10 y 4	<b><sup>88</sup>Rb</b> T <sub>1/2</sub> =17.78 m 11	<b><sup>89</sup>Rb</b> T <sub>1/2</sub> =15.15 m 12	<b><sup>90</sup>Rb</b> T <sub>1/2</sub> =158 s 5

Consistent set of data with calibration points  
(resolved levels, <sup>89</sup>Y + n resonances, etc.)

Relative level densities are indicated by competing channels, which are easily distinguished

---

example:

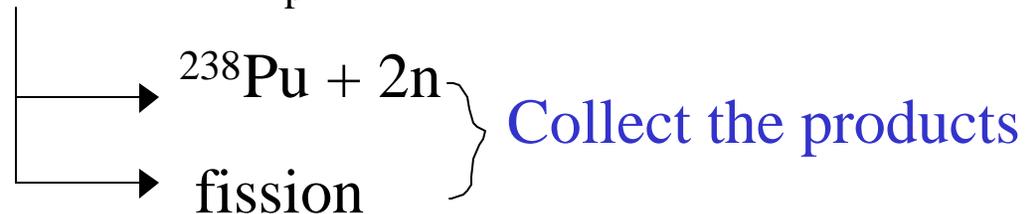

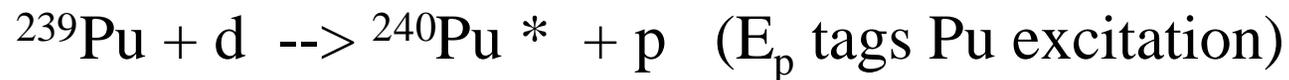

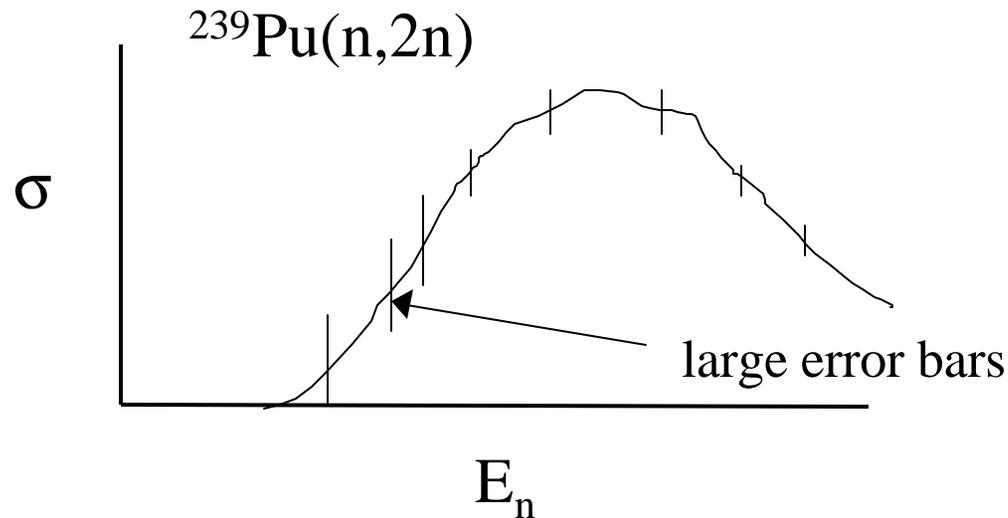

or ...

Then, in inverse kinematics, the products all go forward and can be collected. Ratios of cross sections will result.

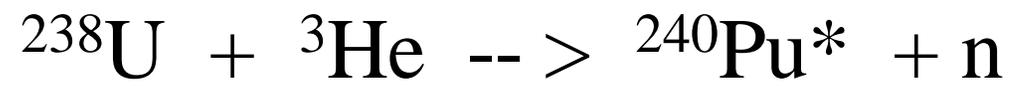

# Fission depends on level density at the fission barrier

---

Inverse kinematics is crucial to this approach!

.... or

etc.

# Conclusions

---

- RIA will be used to study nuclear level densities far from stability
  - level counting
  - emission spectra
  - cross sections for competing channels
- SBSS could benefit greatly from this increased understanding
  - will the studies be in the region of our interests?
