Saturated–unsaturated flow in a compressible leaky-unconfined aquifer

Phoolendra K. Mishra, Velimir V. Vesselinov, Kristopher L. Kuhlman

Abstract
An analytical solution is developed for three-dimensional flow towards a partially penetrating large-diameter well in an unconfined aquifer bounded below by a leaky aquitard of finite or semi-infinite extent. The analytical solution is derived using Laplace and Hankel transforms, then inverted numerically. Existing solutions for flow in leaky unconfined aquifers neglect the unsaturated zone following an assumption of instantaneous drainage due to Neuman. We extend the theory of leakage in unconfined aquifers by (1) including water flow and storage in the unsaturated zone above the water table, and (2) allowing the finite-diameter pumping well to partially penetrate the aquifer. The investigation of model-predicted results shows that aquitard leakage leads to significant departure from the unconfined solution without leakage. The investigation of dimensionless time-drawdown relationships shows that the aquitard drawdown also depends on unsaturated zone properties and the pumping-well wellbore storage effects.

1. Introduction

The assumption that the water flow and storage in the unsaturated zone is insignificant for unconfined aquifer tests was first questioned by Nwankwor et al. [1] and later by Akindunni and Gillham [2] based upon analysis of data collected during pumping tests in Borden, Ontario Canada. Analyzing the collected tensiometer data and soil moisture measurements, the authors concluded that the proper inclusion of unsaturated zone in analytical models used for pumping test analysis would lead to improved estimates of aquifer specific yield. Several analytical solutions were developed that account for the unsaturated zone flow to a pumping well in an unconfined aquifer, taking into account the unsaturated zone [3–5]. These models consider the unsaturated zone effects by coupling the governing flow equations at the water table; the saturated zone governed by the diffusion equation and the vadose zone governed by the linearized unsaturated zone Richards equation, using the linearization of Kroszynski and Dagan [6]. These models considered the limiting case where the pumping well has zero radius. For detailed discussion regarding the fundamental differences between these three models readers are directed to Mishra and Neuman [5].

Drawdown due to pumping a large-diameter (e.g., water supply) well in an unconfined aquifer is affected by wellbore storage [7]. Narasimhan and Zhu [8] used a numerical model to demonstrate that early time drawdown in an unconfined aquifer tends to be dominated by wellbore storage effects. Mishra and Neuman [9] developed an analytical unconfined solution, which considers both pumping-well wellbore storage capacity, and three-dimensional axi-symmetrical unsaturated zone flow. They represented unsaturated zone constitutive properties using exponential models, which result in governing equations that are mathematically tractable, while being sufficiently flexible to be fit to other widely used constitutive models [10–13]. However, Mishra and Neuman [9] considered the unconfined aquifer to be resting on an impermeable boundary and therefore did not account for the potential effects of leakage from an underlying formation (e.g., an aquitard or fractured bedrock). The classical theory of leakage for confined aquifers was originally developed by Hantush [14] assuming steady-state vertical flow in overlying and underlying aquitards and horizontal flow in the pumped aquifer. Hantush [15] later modified the theory of confined leaky aquifers to include transient vertical aquitard flow, giving asymptotic expressions for early and late times. Neuman and Witherspoon [16,17] developed a more complete analytical solution for the more general multiple aquifer flow problem, but did not consider general three-dimensional aquitard flow.

Yatov [18] first investigated the effect of leakage from underlying strata on unconfined aquifer flow. He used the model of Boulton [19] to account for the water table and considered only vertical flow in aquitard. Ehlig and Halepaska [20] investigated leaky-unconfined flow through a finite-difference simulation, which coupled the Boulton [19] and Hantush [14] models to account for leakage across the aquifier-aquitard boundary. Zlotnik and Zhan [21] developed an analytical solution for the flow towards a fully
penetrating zero-radius well in a coupled unconfined aquifer aquitard system where both the unsaturated zone and the horizontal aquitard flow are neglected. Both Zhan and Bian [22] and Zlotnik and Zhan [21] developed analytical and semi-analytical solutions for leakage due to pumping, building on the works of Hantush [14] and Butler and Tsou [23]. Both Zhan and Bian [22] and Zlotnik and Zhan [21] neglect horizontal flow in aquifers. Purely vertical aquitard flow was justified for limiting aquifer/aquitard hydraulic conductivity contrasts by Neuman and Witherspoon [17]. Both Zhan and Bian [22] and Zlotnik and Zhan [21] only consider a vertically unbounded aquitard. Malama et al. [24] developed a solution for three-dimensional aquitard flow in a finite thickness aquitard, but considered the zero-radius pumping well to be fully penetrating and ignored the flow in unsaturated zone. Here, we develop a more general leaky-unconfined aquifer solution by considering a partially penetrating large-diameter well and including the effects of unsaturated zone flow following Mishra and Neuman [9]. The solution is used to investigate the effect of an aquitard on drawdown in overlying unconfined aquifer. We conclude by investigating the effects of wellbore storage capacity and the unsaturated zone on drawdown observed in the aquitard.

2. Leaky-unconfined theory

2.1. Statement of Problem

We consider an infinite radial compressible unconfined aquifer above a finitely thick aquitard (Fig. 1). The aquifer and aquitard are each spatially uniform, homogeneous and anisotropic, with constant specific storage $S_s$ and $S_{s1}$, respectively (a subscript 1 indicates aquitard related properties). The aquifer has a fixed ratio $K_v = K_u/K_r$, between vertical and horizontal saturated hydraulic conductivities, $K_v$ and $K_r$, respectively. The aquitard vertical and horizontal hydraulic conductivities are $K_{z1}$ and $K_{z1}$. The aquifer is fully saturated below an initially horizontal water table at elevation $z = b$. The water table is defined as a $\psi = 0$ isobar where $\psi$ is pressure head. A saturated capillary fringe at non-positive pressure $\psi_a \leq \psi \leq 0$ extends from the water table to the $\psi = 0$ isobar; $\psi_a < 0$ is the pressure head required for air to enter a saturated medium. The saturated hydraulic system (aquitard and aquitard) is at uniform initial hydraulic head $h_0 = b + \psi_a$ before pumping. At time $t = 0$, pumping begins at a constant volumetric flow rate $Q$ from a well of finite radius $r_w$ and wellbore storage coefficient $C_w$ (volume of water released from storage in the pumping well per unit drawdown in the well casing). The pumping well is completed across the aquifer between depths $l$ and $d$ below the aquifer top. Under these conditions the drawdown $s(r,z,t) = h(r,z,0) - h(r,z,t)$ in the saturated zone is governed by the diffusion equation

$$K_v \left( \frac{1}{r} \frac{\partial}{\partial r} \left( r \frac{\partial s}{\partial r} \right) \right) + K_z \frac{\partial^2 s}{\partial z^2} = S_s \frac{\partial s}{\partial t}, \quad r \geq r_w, \quad 0 \leq z < b,$$

along with far-field boundary condition

$$s(\infty, z, t) = 0,$$

the no-flow condition at the portion of the well casing that is not open to the aquifer

$$\left( r \frac{\partial s}{\partial r} \right)_{r=r_w} = 0, \quad 0 \leq z \leq b - l, \quad b - d \leq z \leq b,$$

and the wellbore storage mass-balance expression

$$2\pi K_v (l - d) \left( r \frac{\partial s}{\partial r} \right)_{r=r_w} - C_w \left( \frac{\partial s}{\partial t} \right)_{r=r_w} = -Q, \quad b - l \leq z \leq b - d.$$

Flux is assumed constant across the well screen (see Zhan and Zlotnik [25] for a discussion of this assumption’s validity). The corresponding linearized unsaturated flow equations [5] are

$$K_v k_0(z) \left( \frac{1}{r} \frac{\partial}{\partial r} \left( r \frac{\partial \sigma}{\partial r} \right) \right) + K_z \frac{\partial^2 \sigma}{\partial z^2} = C_0(z) \frac{\partial \sigma}{\partial t}, \quad r \geq r_w, \quad b < z < b + L,$$

where $\sigma(r,z,t)$ is drawdown in the unsaturated zone, $k_0(z)$ is relative permeability and $C_0(z)$ is moisture capacity (slope of the curve representing water saturation as a function of pressure head) functions with the functional dependence limitations on the respective constitutive models

$$k_0(z) = k(\theta_b), \quad C_0(z) = C(\theta_b),$$

where $\theta_b$ is the relative saturation at the air entry point.

![Fig. 1. Schematic representation of leaky unconfined aquifer-aquitard system geometry with finite radius pumping well.](image-url)
where \( \theta_0 \) is the initial volumetric moisture content. Eq. (5) depends on the initial condition

\[
\sigma(r, z, 0) = 0, \quad r \geq r_w
\]

(7)

and the no-flow condition at the well casing

\[
\left( \frac{\partial \sigma}{\partial r} \right)_{r=r_w} = 0, \quad b < z < b + L.
\]

(10)

The interface conditions providing continuity across the water table are

\[
\left( \frac{\partial \sigma}{\partial r} \right)_{r=r_b} = 0, \quad b < z < b + L.

\[
\frac{\partial \sigma}{\partial z} \bigg|_{z=b-L} = 0, \quad r \geq r_w
\]

(9)
\( s - \sigma = 0, \quad r \geq r_w, \quad z = b. \) \hspace{1cm} (11)

\( \frac{\partial \phi}{\partial z} - \frac{\partial \sigma}{\partial z} = 0, \quad r \geq r_w, \quad z = b. \) \hspace{1cm} (12)

The aquitard drawdown \( s_1(r, z, t) \) is governed by

\[ K_1 \frac{1}{r} \frac{\partial}{\partial r} \left( r \frac{\partial s_1}{\partial r} \right) + K_2 \frac{\partial^2 s_1}{\partial z^2} = \frac{\partial s_1}{\partial t}, \quad r \geq 0, \quad -b_1 \leq z < 0. \] \hspace{1cm} (13)

Additionally, aquitard flow satisfies no-flow conditions at the bottom and center of the flow system

\[ \lim_{r \to 0} \left( r \frac{\partial s_1}{\partial r} \right) = \frac{\partial s_1}{\partial z} = 0. \] \hspace{1cm} (14)

The interface condition across the aquifer-aquitard boundary are

\[ s - s_1 = 0, \quad r \geq r_w, \quad z = 0 \] \hspace{1cm} (15)

and

\[ K_s \frac{\partial s_1}{\partial z} = K_t \frac{\partial s_1}{\partial z}, \quad r \geq r_w, \quad z = 0. \] \hspace{1cm} (16)

Like Mishra and Neuman [5], we represent the aquifer moisture retention curve using an exponential function

\[ S_e = \frac{\theta_r - \theta_0}{\theta_e - \theta_0} = e^{\psi_k - \psi_a}, \quad a_e \geq 0, \quad \psi_e \geq 0. \] \hspace{1cm} (17)

where \( \theta_r \) is residual volumetric water content, \( S_p = \theta_r - \theta_0 \) is drainable porosity or specific yield and \( S_e \) is effective saturation. We also adopt the exponential relative hydraulic conductivity model [10],

\[ k(\psi) = \begin{cases} e^{\psi_k - \psi_a}, & \psi \leq \psi_k, \\ 1, & \psi > \psi_k, \end{cases} \quad a_k \geq 0, \quad \psi_k \geq 0, \] \hspace{1cm} (18)

with parameters \( a_k \) and \( \psi_k \) that generally differ from \( a_e \) and \( \psi_e \) in (17). The parameters \( a_k \) and \( a_e \) represent the exponent in the exponential models for hydraulic conductivity and effective saturation, respectively. The parameter \( \psi_k \) represents a pressure head above which relative hydraulic conductivity is effectively equal to unity, which is sometimes but not always equal to the air entry pressure head \( \psi_e \). In addition to rendering the resulting equations mathematically tractable, these exponential constitutive models are sufficiently flexible to provide acceptable fits to standard constitutive models such as those mentioned earlier.

2.2. Point drawdown in saturated and unsaturated zones of aquifer and aquitard

Following Mishra and Neuman [9], it is shown in Appendix A that, drawdown in the saturated zone can be expressed as

\[ s = S_c + S_u, \] \hspace{1cm} (19)

where \( S_c \) is solution for flow to a partially penetrating well of finite radius in a confined aquifer and \( S_u \) is a correction accounting for the underlying aquitard, water table and unsaturated zone effects. The Laplace transformed solution \( S_c \) is given by Mishra and Neuman [9] as

\[ S_c (r, z, p_0) = \frac{Q}{4\pi^2 r_0^2} \phi_0 K_0(\psi_0) + \sum_{n=1}^{\infty} \phi_0 n K_0(\psi_0) \cos[n\pi(1 - z_0)], \]

\[ r_0 \geq r/w, \] \hspace{1cm} (20)

where \( \phi_0 = \frac{\sin(n\theta_0)}{n\sin(n\theta_0)} \), \( \Omega(n) = r_{aw} \phi_0 K_0(\psi_0) + \frac{2}{\pi^2} \frac{n^2 - 1}{n^2} r_{aw}^2 K_0(\psi_0) \), \( \rho_0 = 2/2 \Omega(0) \), \( r_{aw} = r/w \), \( r_0 = r/b \), \( z_0 = z/b \), \( d_0 = d/b \), \( l_0 = l/b \), \( p_0 = pt \), \( C_{aw} = C_w / \left( \pi S_b r_w^2 \right) \), \( t_1 = \alpha_t t/r^2 \), \( p \) is Laplace parameter (the transform of \( t \)), \( \phi_0 = \sqrt{p_{aw}/r_{aw}^2 + \phi_0^2 K_0^2}, \) and \( K_0 \) and \( K_1 \) are second-kind modified Bessel functions of orders zero and one. The Laplace transformed unsaturated zone drawdown \( \sigma \) is given by Mishra and Neuman [9] and is presented in Appendix D for sake of completeness.

The Laplace transformed \( \tilde{s}_u \) derived in Appendix B is

\[ \tilde{s}_u (r, z, p_0) = \int_0^\infty \left( \rho_1 e^{\psi_k - \psi_a} + \rho_2 e^{\psi_k - \psi_a} \right) \frac{r_0 K_0 \rho}{r^2} \int_0^z y^2 \left[ y \phi_1 r_0^2 \right] dy. \] \hspace{1cm} (21)

where

\[ \rho_1 = \left( \frac{1}{(\psi - 1) e^{\psi_k - \psi_a}} - \frac{1}{(\psi - 1) e^{\psi_k - \psi_a}} \right) \frac{\phi_0}{(\psi - 1) e^{\psi_k - \psi_a}}, \quad \rho_2 = \left( \frac{1}{(\psi - 1) e^{\psi_k - \psi_a}} - \frac{1}{(\psi - 1) e^{\psi_k - \psi_a}} \right) \frac{\phi_0}{(\psi - 1) e^{\psi_k - \psi_a}}. \]

Table 1 lists fundamental quantities and Table 2 lists the derived quantities.

The Laplace transformed aquitard drawdown derived in Appendix C is

\[ \tilde{s}_1 (r, z, p_0) = \int_0^\infty \left( \frac{\phi_0}{\phi_0} + \rho_1 + \rho_2 \cosh[\mu_1 (z_0 + R_b)] \right) \times \frac{r_0 K_0 \rho}{r^2} \int_0^z y^2 \left[ y \phi_1 r_0^2 \right] dy. \] \hspace{1cm} (22)

where \( \phi(\psi - \phi_a) \) is the Laplace–Hankel transformed confined aquifer drawdown and is defined in Appendix D. The time domain equivalent \( S_{sc}, S_{su}, S_1 \) and \( \sigma \) of \( S_c, S_u, S_1 \) and \( \sigma \) are obtained through numerical Laplace transform inversion using the algorithm of de Hoog et al. [26].

2.3. Vertically averaged drawdown in piezometer or observation well

Drawdown in an observation well (Fig. 1) that is completed in the aquifer between elevations \( z_{p1} = z_1/b \) and \( z_{p2} = z_2/b \) is found by averaging the point drawdown over screen interval,

\[ s_{sz} - s_{z0} (r, t_1) = \frac{1}{Z_{p2} - Z_{p1}} \int_{Z_{p1}}^{Z_{p2}} s^* (r, z_0, t_1) dz_0. \] \hspace{1cm} (23)

where \( s^* \) can be either aquifer drawdown \( s \), aquitard drawdown \( s_1 \), or a combination of the two, depending on the observation well screen interval.

2.4. Delayed piezometer or observation well response

When water level is measured in a piezometer or observation well having storage coefficient \( C \) the water level observed in the borehole is delayed in time. Following Mishra and Neuman [9], the measured (delayed) drawdown \( s_m \) can be expressed in terms of formation drawdown \( s \) via

\[ s_m = s (1 - e^{-t/r}), \] \hspace{1cm} (24)

where \( t_b \) is basic (characteristic) monitoring well time lag. The dimensionless equivalent of (24) is

\[ s_{m0} = s_0 (1 - e^{-t/r}), \] \hspace{1cm} (25)

where \( t_b = \alpha t_0/r^2 \), and \( r \) is the radial distance to the monitoring location.

3. Model-predicted drawdown behavior

We illustrate the impacts of an underlying aquitard on unconfined aquifer drawdown for the case where \( K_0 = 1, \ S/b/S_a = 10^{-3} \), \( a_{aw} = a_{aw} = 10, \ \phi_{aw} = \phi_{aw} = \phi_{aw}, \ d_0 = 0, \ C_{aw} = 10^3, \ l_0 = 0.6 \) and \( r_{aw} = 0.02 \), where \( a_{aw} = a_{aw}, \ a_{aw} = a_{aw}, \ \phi_{aw} = \phi_{aw} \) and \( \phi_{aw} = \phi_{aw} \). We also
investigate the effects that wellbore storage capacity of the pumping well, the unconfined aquifer, and the unsaturated zone have on aquitard drawdown.

3.1. Dimensionless unconfined aquifer time-drawdown

We start by considering drawdown at two locations in the unconfined aquifer saturated zone, one location closer to water table \((z_0 = 0.75)\) and the other closer to the aquitard-aquifer boundary \((z_0 = 0.25)\). Fig. 2a and b compare variations in dimensionless drawdown \(s_D(r_D,z_D,t_D) = 4\pi K h / Q \sqrt{r_D z_D} t_D\) with dimensionless time at \(z_0 = 0.75\) and \(z_0 = 0.25\) predicted by our proposed solution and the solutions of Mishra and Neuman \([9]\), Neuman \([27]\), and the modified solution of Malama et al. \([24]\) (modified to include the partially penetrating pumping well effects, as done in Malama et al. \([28]\) for a multi-aquifer system). The solutions of Neuman \([27]\) and Malama et al. \([24]\) do not include wellbore storage effects, and therefore they overestimate drawdown at early time. Both of these solutions also ignore the unsaturated zone above the water table, considering the water table a material boundary \([27]\). Our proposed solution follows Mishra and Neuman \([9]\) when leakage effects are minor, but our solution predicts less drawdown when leakage effects are significant. It is seen in Fig. 2b that solution of Mishra and Neuman \([9]\) overestimates drawdown near the aquitard at intermediate time because it does not include aquitard leakage. Near the water table (Fig. 2a) the effects of aquitard leakage are minimal and our proposed solution approaches Mishra and Neuman \([9]\) at all times.

Fig. 3a and b show dimensionless time-drawdown variations at dimensionless radial distance \(r_D = 0.5\) and dimensionless unconfined aquifer saturated zone elevation \(z_D = 0.25\) with different values of \(R_K = K_{z}/K_r\) when the radial aquitard hydraulic conductivity is small \((R_K = K_{z}/K_r = 10^{-6})\) and large \((R_K = 1.0)\). When the radial hydraulic conductivity in aquitard is negligible \((R_K = 10^{-6})\), aquitard flow is predominantly vertical; larger values of vertical aquitard hydraulic conductivity cause decreases in intermediate time drawdown (Fig. 3a). It is seen from Fig. 3b that when aquitard horizontal hydraulic conductivity is large \((R_K = 1)\) the amount drawdown is reduced from further increases in aquitard vertical hydraulic conductivity also extend to the later time.

Fig. 4 depicts the effect of \(R_K\) on the dimensionless time-drawdown at dimensionless radial distance \(r_D = 0.5\) and dimensionless unconfined aquifer saturated zone elevation \(z_D = 0.25\) when \(R_K = 0.1\). Radial flow in the aquitard results in less drawdown at late time than that predicted by Mishra and Neuman \([9]\), who do not account for aquitard leakage.
Fig. 4. Dimensionless leaky-unconfined aquifer drawdown versus dimensionless time at \( r_D = 0.5 \) and \( z_D = 0.25 \) for \( K_D = 1, S/b/S_y = 10^{-3}, \alpha_D = \alpha_0 = 10, \psi_{\alpha_D} = \psi_{\alpha_0}, d_0 = 0, b_0 = 0.6, \theta_0 = 0.6, \theta_{\alpha_D} = 10^{-2}, \theta_{\alpha_0} = 10^{-2} \), and \( R_K \to \infty \) when \( R_k \) varies. Solution of Mishra and Neuman [9] is also shown.

Fig. 5 presents the effect of hydraulic conductivity of an isotropic aquifer on dimensionless time-drawdown at dimensionless time.

Fig. 5. Dimensionless leaky-unconfined aquifer drawdown versus dimensionless time at \( r_D = 0.5 \) and \( z_D = 0.25 \) for \( K_D = 1, S/b/S_y = 10^{-3}, \alpha_D = \alpha_0 = 10, \psi_{\alpha_D} = \psi_{\alpha_0}, d_0 = 0, b_0 = 0.6, \theta_0 = 0.6, \theta_{\alpha_D} = 10^{-2}, \theta_{\alpha_0} = 10^{-2} \), and \( R_K \to \infty \) when \( R_k \) varies and \( R_h = 1 \). Solution of Mishra and Neuman [9] is also shown.

Fig. 6. Dimensionless leaky-unconfined aquifer drawdown versus dimensionless time at \( r_D = 0.5 \) and \( z_D = 0.25 \) for \( K_D = 1, S/b/S_y = 10^{-3}, \alpha_D = \alpha_0 = 10, \psi_{\alpha_D} = \psi_{\alpha_0}, d_0 = 0, b_0 = 0.6, \theta_0 = 0.6, \theta_{\alpha_D} = 10^{-2}, \theta_{\alpha_0} = 10^{-2} \) when \( R_k = b_1/b \) varies. Solution of Mishra and Neuman [9] is also shown.

Fig. 7. Dimensionless aquitard drawdown versus dimensionless time at \( r_D = 0.2 \) and \( z_D = 0.25 \) for \( K_D = 1, S/b/S_y = 10^{-3}, \alpha_D = \alpha_0 = 10, \psi_{\alpha_D} = \psi_{\alpha_0}, d_0 = 0, b_0 = 0.6, \theta_0 = 0.6, \theta_{\alpha_D} = 10^{-2}, \theta_{\alpha_0} = 10^{-2} \), and \( R_K \to \infty \) when \( C_{\alpha_D} \) the dimensionless wellbore storage varies.

Fig. 8. Dimensionless aquitard drawdown versus dimensionless time at \( r_D = 0.2 \) and \( z_D = 0.25 \) for \( K_D = 1, S/b/S_y = 10^{-3}, \alpha_D = \alpha_0 = 10, \psi_{\alpha_D} = \psi_{\alpha_0}, d_0 = 0, b_0 = 0.6, \theta_0 = 0.6, \theta_{\alpha_D} = 10^{-2}, \theta_{\alpha_0} = 10^{-2} \), and \( R_K \to \infty \) when \( a_{\alpha_D} = 1 \) and \( a_{\alpha_0} \) varies.

Fig. 9. Dimensionless aquitard drawdown versus dimensionless time at \( r_D = 0.2 \) and \( z_D = 0.25 \) for \( K_D = 1, S/b/S_y = 10^{-3}, \alpha_D = \alpha_0 = 10, \psi_{\alpha_D} = \psi_{\alpha_0}, d_0 = 0, b_0 = 0.6, \theta_0 = 0.6, \theta_{\alpha_D} = 10^{-2}, \theta_{\alpha_0} = 10^{-2} \), and \( R_K \to \infty \) when \( a_{\alpha_D} = 10^3 \) and \( a_{\alpha_0} \) varies.
radial distance \( r_D = 0.5 \) and dimensionless unconfined aquifer saturated zone elevation \( z_D = 0.25 \). When aquitard hydraulic conductivity is at least two orders of magnitude smaller than the unconfined aquifer, the effects of leakage on the aquifer drawdown are negligible. This is in agreement with findings of Neuman and Witherpoon [16] for confined aquifers. They found errors <5% attributable to the vertical aquitard flow assumption, when the hydraulic conductivity contrast between the aquifer and aquitard was greater than a factor of 100. Fig. 5 also presents a case with the aquitard hydraulic conductivity is larger than the aquifer. Because the proposed model accounts for general three-dimensional flow in underlying zone, we can consider the case where the lower layer is more permeable than the aquifer (\( R_k = 2 \)).

Fig. 6 shows how the dimensionless unconfined aquifer time-drawdown is affected by aquitard thickness. When the aquitard thickness is less than the initial unconfined aquifer saturated thickness (\( R_k \leq 1 \)) aquitard leakage only affects the time-drawdown curve at intermediate time. Fig. 6 shows that further increases in aquitard thickness beyond eight times the initial unconfined aquifer saturated zone thickness have negligible effect on the time-drawdown curve.

### 3.2. Dimensionless aquitard time-drawdown

Fig. 7 depicts dimensionless aquitard drawdown \( S_{Dj}(r_D, z_D, t) = (4\pi K_R b) \frac{Q_j}{r_D Q} (r_D, z_D, t) \) variations with dimensionless time at dimensionless radial distance \( r_D = 0.2 \) and dimensionless aquitard elevation \( z_D = -0.25 \) for different values of \( C_w \). As with solution of Mishra and Neuman [9] for non-leaky systems, aquitard drawdown is impacted by pumping-well wellbore storage capacity. Larger wellbore storage factors result in increased capacity of the wellbore to store water, resulting in a delay in the aquitard time-drawdown, as indicated in Fig. 7.

Fig. 8 depicts the effect that changes in \( a_{D0} \), the dimensionless relative hydraulic conductivity exponent, have on dimensionless time-drawdown at dimensionless radial distance \( r_D = 0.2 \) and dimensionless aquitard elevation \( z_D = -0.25 \). For larger values of \( a_{D0} \), the unsaturated zone hydraulic conductivity decreases more rapidly as pressure becomes more negative, relative to the threshold pressure \( \psi_u \). A diminishing rate of water then drains from the vadose zone into the aquifer; this drainage contributes to reduced aquitard drawdown. For very large \( a_{D0} \), unsaturated hydraulic conductivity quickly decreases once pressure head is below \( \psi_u \), which leads to an much less permeable unsaturated zone.

Fig. 9 shows the effects that changes in \( a_{D0} \), the dimensionless effective saturation exponent, have on dimensionless time-drawdown at dimensionless radial distance \( r_D = 0.2 \) and dimensionless aquitard elevation \( z_D = -0.25 \). When \( a_{D0} \) and \( a_{D0} \) are both large, pressure head and hydraulic conductivity in the vadose zone quickly reduce as pressure reaches the thresholds \( \psi_k \) and \( \psi_u \). The vadose zone can no longer store water, and the water table essentially becomes a moving boundary, which leads to the limiting-case behavior of instantaneous drainage due to Neuman [27]. Consequently, for large values of exponents (Fig. 9, red curve) the proposed solution reduces to that of Malama et al. [24], which relies on the assumption of instantaneous drainage of Neuman [27]. As \( a_{D0} \) decreases, the vadose zone has increased capacity to store water, which diminishes the water table response and aquifer drawdown increases, compared to that predicted by Malama et al. [24].

### 4. Conclusions

Our work leads to the following major conclusions:

1. A new analytical solution was developed for axially symmetric saturated–unsaturated three dimensional radial flow to a well with wellbore storage that partially penetrates the saturated zone of a compressible vertically anisotropic leaky-unconfined aquifer. The solution accounts for both radial and vertical flow in the unsaturated zone and the underlying aquitard.

2. Because the solution considers three-dimensional radial flow in the aquitard, any properties may be assigned to the aquitard, allowing the solution to also be used to simulate leakage from underlying non-aquitard layers (e.g., an unscreened aquifer region with different hydraulic properties).

3. Aquitard leakage can lead to significant departures from solutions that do not account for leakage, e.g., Mishra and Neuman [9]. However, the effect of leakage on unconfined aquifer drawdown diminishes at points farther away from the aquifer-aquitard boundary.

4. Unsaturated zone effects are often more important than leakage effects when the observation location is close to the water table.

5. For large diameter pumping wells, at early time water is withdrawn entirely from the wellbore storage. Solution that do not account for wellbore storage predict a much larger early rise in drawdown.

6. Aquitard drawdown is also affected by the pumping-well wellbore storage capacity. As in the unconfined aquifer, larger wellbore storage capacity leads to larger impacts on the observed aquitard drawdown.

7. The unsaturated zone properties not only affect the unconfined aquifer time-drawdown behavior but they also impact the observed aquitard response.

### Appendix A. Decomposition of saturated zone solution

In a manner analogous to Mishra and Neuman [5] we decompose \( s \) into two parts

\[
s = s_C + s_U, \quad (A.1)
\]

where \( s_C \) is solution for a partially penetrating well in a confined aquifer, satisfying

\[
\frac{1}{r} \frac{\partial}{\partial r} \left( r \frac{\partial s_C}{\partial r} \right) + K_D \frac{\partial^2 s_C}{\partial z^2} = \frac{1}{a_C} \frac{\partial s_C}{\partial t} , \quad r \geq r_w, \quad 0 \leq z < b, \quad (A.2)
\]

\[
s_C(r, z, 0) = 0, \quad r \geq r_w, \quad (A.3)
\]

\[
s_C(\infty, z, t) = 0, \quad (A.4)
\]

\[
\frac{\partial s_C}{\partial z} \bigg|_{z=0(b)} = 0, \quad r \geq r_w, \quad (A.5)
\]

\[
\frac{\partial s_C}{\partial t} \bigg|_{t=t_w} = 0, \quad 0 \leq z \leq b - l, \quad b - d \leq z \leq b, \quad (A.6)
\]

\[
2\pi K_l (l - d) \frac{\partial s_C}{\partial t} \bigg|_{t=t_w} - C_W \frac{\partial s_C}{\partial t} \bigg|_{t=t_w} = -Q, \quad b - l \leq z \leq b - d \quad (A.7)
\]
and $s_U$ is a solution that takes into account aquitard and saturated–unsaturated unconfined conditions, but has no pumping source term, satisfying

$$1 \frac{\partial}{\partial r} \left( \frac{\partial s_U}{\partial r} \right) + K_0 \frac{\partial^2 s_U}{\partial z^2} = \frac{1}{r} \frac{\partial s_U}{\partial r}, \quad r > 0, \quad 0 \leq z < b.$$  

(A.8)

$$s_U(r, z, 0) = 0, \quad r > 0.$$  

(A.9)

$$s_U(\infty, z, t) = 0.$$  

(A.10)

$$\frac{\partial s_U}{\partial z} - K_1 \frac{\partial s_U}{K_z \partial z} = 0, \quad r > 0, \quad z = 0,$$  

(A.11)

$$\frac{\partial s_U}{\partial z} \bigg|_{z=0} = 0, \quad 0 \leq z \leq b.$$  

(A.12)

subject to interface conditions at water table,

$$s_C + s_U - \sigma = 0, \quad r \geq r_u, \quad z = b,$$  

(A.13)

$$\frac{\partial s_C}{\partial z} + \frac{\partial s_U}{\partial z} - \frac{\partial \sigma}{\partial z} = 0, \quad r \geq r_u, \quad z = b.$$  

(A.14)

where the first term is zero by definition of $s_C$.

**Appendix B. Laplace-space solution for saturated zone**

Eqs. (A.8)–(A.14) are solved by sequential application of the Hankel transform

$$f(a) = \int_0^\infty r f(r) J_1(\alpha r) dr$$  

(B.1)

and Laplace transform

$$f(p) = \int_0^\infty f(t) e^{-pt} dt,$$  

(B.2)

with Hankel parameter $\alpha$ and Laplace parameter $p$, $r$, $f(r)$ being zero-order Bessel function of the first kind.

The Laplace–Hankel transform of confined aquifer solution [9] is

$$\tilde{s}_r(\alpha, \omega, p_0) = C_0 \left\{ \frac{r \omega}{\alpha} J_1(\alpha r_0 \tau_0) + \frac{r \omega}{\alpha} J_1(\alpha r_0 \tau_0) \right\} \left[ \frac{r \omega}{\alpha} J_1(\alpha r_0 \tau_0) - \frac{r \omega}{\alpha} J_1(\alpha r_0 \tau_0) \right]$$

$$+ \sum_{n=1}^{\infty} C_n \left\{ \frac{r \omega}{\alpha} J_1(\alpha r_0 \tau_0) + \frac{r \omega}{\alpha} J_1(\alpha r_0 \tau_0) \right\} \left[ \frac{r \omega}{\alpha} J_1(\alpha r_0 \tau_0) - \frac{r \omega}{\alpha} J_1(\alpha r_0 \tau_0) \right]$$

$$+ \frac{\cos(\pi \alpha \tau_0 (1 - \pi \alpha \tau_0))}{\pi \alpha \tau_0}.$$  

(B.3)

where $\tau_0 = \sqrt{\rho S_r / K_r}$ and $\tau_0 = \sqrt{\rho S_r / K_r + Ko n^2 \pi^2 / b^2}$.

The Laplace transform of Eqs. (A.8)–(A.14) is

$$1 \frac{\partial}{\partial r} \left( \frac{\partial \tilde{s}_r}{\partial r} \right) + K_0 \frac{\partial^2 \tilde{s}_r}{\partial z^2} - \frac{p}{\alpha} \tilde{s}_r, \quad 0 \leq z < b,$$  

(B.4)

$$\tilde{s}_r(\infty, z, p) = 0,$$  

(B.5)

$$\left. \frac{\partial \tilde{s}_r}{\partial z} \right|_{z=0} = K_1 \frac{\partial \tilde{s}_r}{K_z \partial z},$$  

(B.6)

$$\left. \left( r \frac{\partial \tilde{s}_r}{\partial r} \right) \right|_{r=0} = 0, \quad 0 \leq z < b,$$  

(B.7)

$$\tilde{s}_C + \tilde{s}_U - \tilde{\sigma} = 0, \quad z = b,$$  

(B.8)

$$\frac{\partial \tilde{s}_C}{\partial z} + \frac{\partial \tilde{s}_U}{\partial z} - \frac{\partial \tilde{\sigma}}{\partial z} = 0, \quad z = b,$$  

(B.9)

where the first term is zero by definition of $\tilde{s}_C$.

Taking the Hankel transform of Eqs. (B.4)–(B.9) yields

$$-a^2 \tilde{s}_U + K_0 \frac{\partial^2 \tilde{s}_U}{\partial z^2} = \frac{P}{\alpha} \tilde{s}_U, \quad 0 \leq z < b,$$  

(B.10)

$$\tilde{s}_U + \tilde{\sigma} = 0, \quad z = b,$$  

(B.11)

$$\frac{\partial \tilde{s}_U}{\partial z} \left. + \frac{\partial \tilde{\sigma}}{\partial z} = 0, \quad z = b,$$  

(B.12)

$$\frac{\partial \tilde{s}_C}{\partial z} + \frac{\partial \tilde{s}_U}{\partial z} - \frac{K_1}{K_z} \frac{\partial \tilde{s}_1}{\partial z} = 0, \quad z = 0.$$  

(B.13)

The general solution of (B.10) subject to (B.11) is

$$\tilde{s}_U = \rho_1 e^{\eta z} + \rho_2 e^{-\eta z},$$  

(B.14)

where $\rho_1$ and $\rho_2$ are coefficients to be determined from boundary conditions.

Considering that $\partial \tilde{s}_U/\partial z = 0$ at $z = 0$ and $z = b$ by virtue of (A.5) and that

$$\frac{\partial \tilde{s}_U}{\partial z} \bigg|_{z=b} = \tilde{q}(\tilde{s}_C + \tilde{s}_U)_{z=b},$$  

(B.15)

which, together with $q$, are derived in (D15) of Mishra and Neuman [9] and

$$\frac{\partial \tilde{s}_U}{\partial z} \bigg|_{z=0} = q_s (\tilde{s}_C + \tilde{s}_U)_{z=0},$$  

(B.16)

which, together with $q_s$, are derived in (C.7) we obtain from Eqs. (B.11)–(B.13)

$$\rho_1 = \frac{q_1 (\eta + q_1) e^{-\eta b} \tilde{s}_C(z = 0) - q_1 (\eta + q_1) \tilde{s}(z = b)}{\Delta}$$  

(B.17)

$$\rho_2 = \frac{q_1 (\eta - q_1) e^{-\eta b} \tilde{s}_C(z = 0) - q_1 (\eta - q_1) \tilde{s}(z = b)}{\Delta},$$  

(B.18)

where $\Delta = (\eta - q_1) (\eta + q_1) e^{-\eta b} - (\eta - q_1) (\eta + q_1) e^{\eta b}$.

The inverse Hankel transform of (B.14) is

$$\tilde{s}_U = \int_0^\infty (\rho_1 e^{\eta z} + \rho_2 e^{-\eta z}) a_0 (ar) d\alpha.$$  

(B.19)

Defining a new variable $y = ar/K_0^{1/2} r_0$, transforms (B.19) into the result presented in (21). It is noted that when $q = 0$ the aquitard is replaced by an impermeable boundary, and $\rho_1 = \rho_2 = 2q_s (\tilde{s}_C(0) - \tilde{s}_H(1)) \cos(\eta b_1)$.

These simplifications reduce (B.19) to Eq. (3) of Mishra and Neuman [9].

**Appendix C. Aquitard solution**

Laplace–Hankel transform of governing flow equations for aquitard are

$$-a^2 \tilde{s}_1 + K_0 \frac{\partial^2 \tilde{s}_1}{\partial z^2} = \frac{S_{11}}{K_1} z_1,$$  

(C.1)

By virtue of no flow boundary at the bottom of the system, 

$$\frac{\partial \tilde{s}_1}{\partial z} \bigg|_{z=b} = 0,$$  

the general solution to (C.1) is

$$\tilde{s}_1 = \rho_1 \cosh(\eta_1 (z + b_1)),$$  

(C.2)

where $\eta_1^2 = \frac{a^2}{K_1} + \frac{p S_{11}}{K_1^{1/2} r_0}$. The boundary condition

$$\tilde{s}_1(z = 0) = \tilde{s}_H(z = 0) = (\tilde{s}_C + \tilde{s}_U)_{z=0}$$  

(C.3)

gives

$$s_1 = \frac{(\tilde{s}_C + \tilde{s}_U)_{z=0}}{\cosh(\eta b_1)} \cosh(\eta b_1).$$  

(C.4)

Using (B.13) transforms (C.4) into the solution presented in (22). The derivative of (C.4) is
\[ \frac{ds}{dz} = \eta_1 \tanh(\eta_1 b_1)(\tilde{s}_C + \tilde{s}_U) \quad z = 0. \tag{C.5} \]

The flux boundary condition at the aquifer–aquitard interface
\[ \frac{\partial s}{\partial z} \bigg|_{z=0} = \frac{K_z}{K_{zU}} \frac{\partial \tilde{s}}{\partial z} \bigg|_{z=0}. \tag{C.6} \]

Combined with (B.9) gives
\[ \frac{\partial \tilde{s}}{\partial z} \bigg|_{z=0} = q_1 (\tilde{s}_C + \tilde{s}_U) \bigg|_{z=0}, \tag{C.7} \]

where \( q_1 = \frac{K_0}{K_z} \eta_1 \tanh(\eta_1 b_1). \)

### Appendix D. Laplace transformed unsaturated zone drawdown

Laplace transformed drawdown \( \sigma \) in the unsaturated zone are given by Mishra and Neuman [9] as
\[ \sigma(r_D, z_D, p_D) = \left\{ \begin{array}{ll}
\int_0^\infty & y_0 r_D dJ_1(y_0 r_D b_D) K_0(r_D \phi_0) + \Gamma(0) \\
0 & \text{for } a_D \neq a_D^0
\end{array} \right. \]
\[ + \sum_{n=1}^{\infty} C_n \frac{r^2}{K_D b_D} \left\{ y_0 r_D dJ_1(y_0 r_D b_D) K_0(r_D \phi_0) + \Gamma(n) \right\}, \tag{D.2} \]

where
\[ \Gamma(n) = \frac{\alpha y_0}{r_D} J_0(2 r_D b_D) K_0(r_D \phi_0) + \frac{\alpha}{r_D} \quad \text{and} \quad J_0 \text{ and } J_1 \text{ being Bessel functions of first kind and, orders zero and one; } \]
\[ \chi = \left\{ \begin{array}{ll}
\left[ \frac{\alpha y_0}{r_D} J_0(2 r_D b_D) K_0(r_D \phi_0) + \frac{\alpha}{r_D} \right] & \text{for } a_D \neq a_D^0, \\
\left[ \frac{\alpha y_0}{r_D} J_0(2 r_D b_D) K_0(r_D \phi_0) + \frac{\alpha}{r_D} \right] & \text{for } a_D = a_D^0, L_D \to \infty, \\
0 & \text{for } a_D = a_D^0, L_D \to \infty. \tag{D.3} \]

\[ q_D = \left\{ \begin{array}{ll}
\frac{\alpha y_0}{r_D} J_0(2 r_D b_D) K_0(r_D \phi_0) + \frac{\alpha}{r_D} & \text{for } a_D \neq a_D^0, \\
\left[ \frac{\alpha y_0}{r_D} J_0(2 r_D b_D) K_0(r_D \phi_0) + \frac{\alpha}{r_D} \right] & \text{for } a_D = a_D^0, \tag{D.4} \end{array} \right. \]

where \( L_D = L/b_D, J_0 \) and \( \phi_0 \) being first and second kind Bessel functions of order \( n \).
